Treatment of Typhus at Freiburg.—Baumgärtner, after trial of different methods, relies upon the expectant method as the best. At the commencement he ventures on an emetic, and he is inclined to think that it has occasionally cut short the disease; but on this point he speaks doubtfully, as the cases thus treated successfully might not have been true examples of the disease. Many cases of typhus have been treated without administer any potent remedy throughout the whole course of the disease. Small doses of ipecacuanha, or liq. ammon. acet., have been given, and these because patients are apt to lose confidence and be dispirited unless something medicinal be done. The cases in which the expectant method was adopted were those in which the excretions were not suppressed, in particular those in which there were urinary deposits. In the first stage of cases complicated with pneumonia and bronchitis, large doses of calomel were given, and, occasionally, a general bleeding; but in the second stage the calomel was found to be decidedly hurtful. In cases of great prostration, wine was administered freely; and where the pulse was intermittent, and cramps present, the patient was put in a cold-bath, cold effusions applied to the head, and mu k administered.

Development of the Skeleton.—Baumgärtner applies the Dualistic theory, now advocated in Germany by numerous physiologists, to the development of the skeleton, and propounds the doctrine that the latter is neither more nor less than a double ossific cell. He endeavours to show that an animal, at first, consists of one cell only, and that this divides into two cells—an anterior and posterior—enclosed in a common membrane. Each of these divide into two lateral halves, and into an upper and lower half, and then into further subdivisions; on one side the brain and spinal cord being developed with the posterior apical column and the connected ganglia; on the other, the anterior apical column, the lungs, and abdominal viscera. From each of

the two primary body-cells four projections arise—those springing from the posterior cell being developed into the upper and lower jaw, those from the anterior corresponding to the four extremities.

Post-mortem Appearances in a Case of Typhilitic Stenosis.—Dr. Günzburg, in his "Pathological Histology," cited in "The British and Foreign Review," gives the following:—"The walls of the caecum were of double their ordinary volume; the peritoneal coat was covered with vessels full of dark blackish blood, especially towards the iliac end. The appendix vermiformis, on being opened, presented a horseshoe shape; the mucous membrane of its lower portion was of a pale grey colour, thickened, and presented numerous minute depressions, some of which were isolated, while others were associated into a sort of network. The upper portion was divided by a band into two diverticula, in each of which the mucous coat was converted into a gangrenous capsular membrane, enclosing a hard concretion. The concretion in the lower diverticulum had the form and size of a date kernel, and was of a bright yellow colour, but soon became brown on exposure to air. The diseased surface was covered by a thin layer of finely granular, yellowish-green matter, in which were detected a large number of four-sided rhombic prisms, scarcely averaging .02 of a millimeter in length—fragments having the form of imperfectly round nucleoli, and in some instances surrounded by a capsule; a quantity of cylinders anastomosing at certain points and presenting occasional contractions and dilatations. These cylinders were both filled and surrounded with spherical corpuscles, having a diameter of .006 of a millimeter, and by immeasurably minute molecular granules, which, when accumulated, presented a blackish-green appearance. On this layer of finely granular matter there was a brownish, very injected membrane. In the fibrous network there were numerous engorged capillaries, inflammatory cells, and crystals. The peritoneal coat, which could not be very clearly made out, was covered with crystalline fragments, and penetrated by numerous injected vessels; inflammatory cells could be observed between its elastic fibres. Hence typhilitic stenosis is characterized by an extremely rapid exudative inflammatory process, occurring simultaneously in all the coats of the affected part, and dependent on mechanical irritation. To this follows gangrene, in consequence of the destruction of the supplying vessels; and hence the disintegration, not only of the normal elementary constituents, but also of the inflammatory products, into molecular particles. At the same time the inorganic elements of these tissues assume the crystalline form."

Glands found in the Mucous Membrane of the Larynx.—Günzburg describes them as follows:—"Simple grape-shaped glands filled with cells, and devoid of an excretory duct. Ramifying grape-shaped glands, grape-shaped glands with an excretory duct. The cells investing the glands studded with barbed and curved cilia. Simple flask-shaped glands, formed of several epithelial cells lying over one another, and filled with inflammatory cells. On their apices are one or more ciliated cells. Double flask-shaped glands, or several simple glands lying on one another, sometimes having an excretory duct in the form of an inverted cone. The glands often attain to a length of .25 and a breadth of .3 of a millimeter. They are full of cells varying in diameter from .007 to .01 of a millimeter, with a nucleus and several nucleoli, which entirely prevent us from distinguishing the construction of the glands. After their removal the tissue is even to be composed of accurately-fitting cells of pavement epithelium, with nuclei having a diameter of .006 of a millimeter. Sometimes there are also removed the nuclei of glandular epithelium, analogous in all respects to inflammatory cells, and the glands then exhibit simply a homogeneous membrane strewed with blackish specks. The cylindrical epithelium to which the cilia are attached, the pavement epithelium, and those cells which are newly formed in the glands, con-

stitute the greater portion of the expectoration in cases of inflammation of the mucous membrane of the larynx."

Treatment of Chronic Hydrocephalus.—Gólis, of Vienna, recommends the hair of the child's head to be cut very close, and a drachm or two of mild mercurial ointment to be rubbed in every day, and the head covered with a flannel cap. Small doses of calomel are to be administered unless diarrhoea should supervene, when the ointment alone is to be used. This plan is to be continued for five or six weeks, and, if with benefit, the remedies are to be gradually discontinued, though the cap is to be worn for some time after the ointment has ceased to be used. If the disease does not yield to this treatment after the above-mentioned time, issues may be inserted into the back of the neck.

The Purposes of Lactic Acid in the Animal Economy.—Liebig says that this acid is employed to support the respiratory process; and the function performed by sugar, starch, and in general, all those substances which, in contact with animal matter, are convertible into lactic acid, seems to be an hypothesis. These substances are convertible in the blood into lactates, which are destroyed as fast as they are produced, and which only accumulate where the supply of oxygen is less, or where some other attraction is opposed to the agency of that element.

REVIEWS.

Report on the Climate and Principal Diseases of the African Station, compiled from Documents in the Office of the Director-General of the Medical Department, and from other sources, in compliance with the directions of the Right Honourable the Lords Commissioners of the Admiralty. Under the immediate direction of Sir William Burnett, M.D., K.C.H., F.R.S. By ALEXANDER BRYSON, M.D., Surgeon R.N. London, 1847; pp. 260.

The great scourge of the naval force employed on the African station is remittent fever, a disease which prostrates the energies and destroys the lives of both officers and men. Its virulence is manifested amongst those crews which have frequent communication with the shore, and the disease often breaks out in vessels cruising off the land, though it seldom then presents such malignant characteristics. It is the opinion of Dr. Bryson that, if the duties of the station could be performed without approaching at any time within a few miles of the shore, the mortality would be very greatly reduced. A beneficial change would evidently result, not only from the men being less exposed to miasmatic exhalations, but from their being prevented indulging in those acts of intemperance which, in any climate, would act prejudicially on the health, especially in such a one as that which is found on the coast of Africa. That certain agents, either aerial or telluric, act in producing fever is evident from the facts brought forward in the work before us, as well as from the evidence of others who have been well qualified to give an opinion on the subject; but the liability of the European constitution to suffer from these causes is greatly increased by agencies over which control can be exercised.

Before entering more fully into a consideration of the latter agencies, it will be proper to advert to the nature of the climate of the African station. Here our author touches upon the doctrines which have been advanced from time to time by those who have had experience in the matter, and those who have had none, respecting the effects of certain supposed abnormal conditions of the atmosphere in the production of disease, especially the fevers of the country. The conclusion at which Dr. Bryson arrives is, that the "cause" is not absolutely and essentially a malarious production, but rather that it exists equally in dry and marshy places; although in the latter, from some contingent local cause impairing the general health, such as abounds on all

parts of the coast, the system becomes more susceptible of its influence:—

"The temperature along the interior shores of Africa is much more equable than seems to be generally supposed. From the Gambia, on the north, to Benguela on the south, of the equator, the general range in the hottest part of the year is between 80° and 86° in the shade on board ship, even in the most central of the equatorial regions, while on the extremes of the station, during the winter months, it rarely falls below 58°; during a tornado, however, on a part of the station, it will sometimes fall in the course of a few minutes from its maximum of 75°, rising again gradually to its natural standard as soon as the storm has passed away. These latter sudden transitions may occasionally bring on a paroxysm of fever in the debilitated and aguish; but it is seldom, even when they come from the land loaded with dust and the aroma of a thousand plants, that they produce what may be called a regular attack of fever, or otherwise interfere with health; by cooling and clearing the atmosphere, they have rather an agreeable and an invigorating effect upon those whose constitutions are still unimpaired."

Occasionally there is a "muggy" condition of the atmosphere, which produces such physical prostration as disqualifies for even the most passive employments or amusements. It appears to be the result of an almost total cessation of the usual evaporation from the skin, which constantly remains covered with an unobtrusive clammy perspiration, exceedingly disagreeable. This state of the atmosphere is chiefly observable after the rains, when the "smokes" commence; these are dense masses of vapour which sometimes envelop the land for days together, either generally or partially, and, being driven seaward by the wind, are supposed, without proof, to bear with them the exciting principle of fever. At this time wet clothes retain their moisture day after day. Boots, shoes, leather belts, &c., are speedily covered with a thick mould, and rapidly decay. Iron rusts with rapidity, while at the same time the great increase of minute animal and vegetable life shows the aptitude of all substances to pass from the inorganic into the organic state.

The effects of the harmattan upon the vegetable kingdom are more conspicuous than upon the animal: trees appear to be suddenly blighted and stripped of their leaves, grass withers, the parched earth is rent in every direction, out of which it was supposed a noxious malaria issued; but, unfortunately for this theory, these are the most healthy seasons of the year to Europeans. The direct rays of the sun do not appear to be either oppressive or dangerous; and the influence of the moon is only worthy of notice in a secondary point of view by its action on the tides, which materially affects health. During the springs the greatest reflux of water into the estuaries of all large tidal rivers produces a large increase of marsh surface, and, consequently, a corresponding increase in miasmatic exhalations; hence it is thought that at these times fevers are more prevalent. It appears, therefore, that the African climate differs only from others in the same degrees of latitude in its greater humidity.

The boat service is mentioned as one of the most prolific sources of disease on the station. Officers and men appear ready to embark in any enterprise that offers a chance of adventure or a change of life, without the slightest regard to ulterior consequences. Here the cooking is often indifferent, and frequently dispensed with altogether, pork being sometimes eaten raw as it comes from the tub, and rum, for the want of water, frequently drunk in an undiluted state; thus producing, independent of the most adverse climatorial agencies, such functional derangement as tends to the general deterioration of health, and sooner or later to the induction of organic disease.

In illustration of this part of the subject, we quote the case of the *Atna*, which arrived on the coast from England in December, 1843, for the purpose of resuming the survey in the

parallels 11° and 12° N. :—"On the 8th of January her tender, the Raven, with the boats of the ship, proceeded to survey the river Cachca; and having been employed in this duty for a few days, ascending the latter, they arrived at Farine, where they remained thirty-six hours; they then descended the river, and joined the *Etna* on the 22nd of the same month. The weather during the time was close and sultry by day, but cold during the night; the thermometer at noon averaging 83° in the shade. The rise and fall of the tide are considerable, and the banks, which are muddy and shelving, extensively exposed at low water. The boats which were thus employed contained ten officers and forty-two seamen, seventeen of whom contracted fever, namely, four officers and thirteen seamen, and six died. The whole were attacked between the 27th of January and the 6th of February. The ship, on the suggestion of the surgeon, left the coast on the 4th of the latter month, ran for the Cape Verde Islands, and anchored in Porto Praya on the 8th, where the sick rapidly recovered. The disease, in some instances, was attended with yellowness of skin; but it is not stated whether black vomit took place in any of the fatal cases. Bleeding, purgatives, and diaphoretics were the principal remedial means used."

A very singular circumstance has been observed in men who have been long away upon boat expeditions: when they returned and reached the deck of their own vessel, they have been seen to reel and stagger, as if they were under the influence of spirits, from weakness, giddiness, &c., affording strong proofs of the severity of the service. The boats, moreover, when long absent, have been quite sodden with water, and their bottoms covered with seaweed.

A foul state of the hold often is a very prolific source of fever, though it does not follow that, because a ship has an offensive hold, she will be sickly; yet prudence would dictate that those places should be cleared out in some harbour where the labour might be conducted without risk to the men.

The accumulation of heaps of rubbish at the bottom of a ship is oftentimes astonishing, where, by the heat of the climate and the action of the salt water, they rapidly decay, and form a blackish mud, not dissimilar to that observed amongst the roots of mangrove thickets on the banks of rivers within the influence of the tide; it sometimes even acquires a consistence sufficient to block up the passage of the timbers.

In the case of the *Conflict*, which had thirty cases of fever, eight of which proved fatal on board, the hold was in a most filthy state. It is true that the invasion of the disease and the subsequent mortality are attributed to the exposure of the crew on shore during heavy rains, excess, and frequently sleeping in the open air; yet it is not improbable that causes within the ship might have been at work to give to the disease its malignant character. The fever was remittent, its symptoms varying in different cases.

"This vessel sailed from Sierra Leone on the 6th of August, and arrived at Ascension on the 29th, where, in consequence of a representation which was made to the commodore, relative to the state of the vessel below, it was directed that she should be thoroughly cleaned out. On the removal of the tanks and the limber boards the hold presented a very filthy appearance, blackish mud with vegetable matter being brought into view, the effluvium from which was at first insufferable. The passages of the pump-well were found to be completely blocked up. This filth having been removed, the holds were white-washed, well ventilated, and dried; the tanks were then restowed, and her stores embarked, after which she again sailed for the coast, where she arrived on the 11th of October, and resumed her duties on the *Bights*." This vessel was retained for a short time in active service, but being found defective, and the crew, from disease and want of discipline, being in a disorganized state, the latter were sent to England, and the vessel made a hulk for the reception of prize crews.

In the case of the *Heroine*, employed upon

the Benguela division of the station during the early part of the year 1844, fifteen cases of fever occurred, of which four were contracted whileumping out the hold of a leaky alaver in the harbour of St. Paul de Loando; and these were the worst. Three of the men were seized while at work, while the fourth did not present symptoms of disease until eight days afterwards. Two of the men died. The *Bonetto* is described as being in a filthy condition, the stench from the holds being almost insupportable; and that, on subsequently clearing her out, the corn and yams with which she was freighted were found to be in a state of decomposition. In this vessel the commander, master, purser, assistant-surgeon, and twenty-eight seamen and marines had fever, of whom twenty-eight recovered, three were invalided and sent to England, and eight died. In the *Eclair*, so celebrated on account of the dreadful fever which prevailed amongst her crew, though the holds were supposed to have been made perfectly clear at Bonna Vista, there was afterwards found, when she was recommissioned, a large collection of mud, fully three inches in depth, upon that portion of her bottom occupied by the boilers and machinery, which apparently had not been disturbed for a long time. It is no uncommon thing for an epidemic to become aggravated by opening the holds of a ship within the tropics.

Green firewood is mentioned by Dr. Bryson as favourable to the production of disease on board when closely stowed: it becomes heated, and emits a very disagreeable effluvia. The *Vestal*, in the year 1839, had a quantity of green wood on board, from which there arose so unpleasant a smell as to annoy the men at work in the hold; and when the wood was got up on deck to be stripped of its bark, the fever then prevalent on board seemed to become more virulent and fatal, while the men employed in stripping off the bark were all within two or three days seized with the disease in an aggravated form. As a measure of precaution, it is recommended in unhealthy climates to have wood denuded of its bark, split into moderate-sized pieces, and partly charred, previously to being sent on board.

Intemperance, as a source of disease, has been adverted to, when speaking of Sierra Leone, where its influence upon the men landed there is more particularly observable. "Unfortunately," says our author, "this vice is so firmly, although artificially, engrafted upon the nature of our seamen, that there is but little hope of its being even partially eradicated, until the daily issue of spirits in her Majesty's service be either totally discontinued, reduced in quantity, or issued only at more distant periods; and, so long as the naval service is recruited from the merchant shipping, until the infamous system there practised, of plying men with ardent spirits for the purpose of nefariously exacting an undue amount of labour from them, be also discontinued."

From the medical reports it is evident that remittent fever is the dreadful scourge of the African coast. It prevails at all times as an endemic, and at distant and uncertain periods occasionally assumes an epidemic form. In some cases the remittent character of the disease was well marked; in others it was more obscure. In some there were indications of local congestion affecting one or other of the principal organs while in others these symptoms were not present. It would be superfluous to enter into a detailed account of the symptoms; and we proceed to notice the medical treatment recommended. Emetics, we are informed, are occasionally had recourse to, apparently with benefit, when the attack is observed to be developed after a full meal; in an advanced stage of the disease they are inadmissible, from the danger of causing an irritable state of the stomach. Bleeding is viewed in rather a suspicious light; it is, however, recommended when the fever is accompanied by unequivocal symptoms of inflammation, the amount of depletion being strictly limited to the apparent exigency of the case—the operator guarding himself against being led

away by the idea of subduing the febrile action by lessening the quantity of the vital fluids; so that they are frequently either so destructively superabundant, or so irregularly distributed, as to require reduction. "Fever," our author observes, "on the coast does not require a different mode of treatment from that pursued for fever in this country. Bleeding is seldom necessary after the first twenty-four hours from the commencement of the fever, and certainly never after forty-eight. If the blood drawn exhibits a deficiency of colouring matter, and a loose imperfectly-formed clot, it would be imprudent to repeat the operation, however high the symptoms ran. An early exhibition of cathartics is recommended, as the alimentary canal is generally in a loaded state; but, when often repeated, may induce a vitiated state of the secretions, and thus produce an effect it was desired to obviate. During the earlier stages of the disease, when the stomach is in an irritable state, a simple dose of calomel has sometimes had the effect of arresting vomiting; in the same dose it has also been useful as a purgative, having frequently, from its small bulk, been retained when every other cathartic was rejected. In the more advanced stages it has been given in combination with the disulphate of quinine, when it was considered desirable to keep up the specific action of the mineral, and at the same time necessary to have recourse to tonics. It is a mistaken notion to suppose that calomel is a specific; and pyralism is not to be hastened, however great the quantity of mercury absorbed. Of all the remedies employed in fever, or in its sequelæ, upon the west coast of Africa, there is not any so unequivocally valuable as the disulphate of quinine. The most approved time to commence its administration in the remittent is the moment a perfect state of apyrexia is observed. It is usually given to the extent of from two to four grains every fourth or fifth hour, dissolved in water slightly acidulated with dilute sulphuric acid, or in white wine. When it fails in arresting the irregular intermissions which succeed the common endemic or the epidemic, it is seldom that any other medicine will succeed. Blisters are only useful to the head or nape of the neck when the brain is much affected from sanguineous congestion, and to the epigastrium, to relieve pain or check vomiting. Cold sponging, either generally or partially, is often resorted to when the fever runs high, with great heat of surface, and in most instances with considerable temporary relief."

The means employed for remedying the mischiefs arising from foul holds are, after cleansing, the use of the solution of the chloride of zinc, which appears to be a very valuable agent in destroying those noxious emanations proceeding from the bilge-water, mixed as it is with so much matter in a state of decomposition.

It appears, from table 22 of the volume, that "the annual ratio of mortality from disease alone on the African station for a period of twenty-one years was 54.4 per 1000 of the mean force employed. The fatal nature of the climate, however, becomes more apparent when placed in juxtaposition with the mortality on other stations, viz. :—

South America ..	7.7
Mediterranean ..	9.3
Home ..	9.8
East Indies ..	15.1
West Indies ..	18.1
Coast of Africa ..	54.4

"It is proper, nevertheless, to observe that nearly one-half of this proportional amount resulted from epidemic fever alone, which was confined to a few vessels of the squadron during the years 1828-9 and 30; again in 1837-8 and 39; and in the *Eclair* in 1846. Deducting the loss from epidemic fevers, therefore, the ratio of mortality from all other classes of disease on the station will be about 20.0 per 1000 of the mean force annually; this, however, can give no adequate idea of the permanent loss of health, which is assumed to be great. Still, from these and other data, it seems fair to deduce that if

boat service were in some degree restricted—if prize crews were not permitted to land at Sierra Leone—and if all vessels contracting epidemic disease were to leave the station, and proceed directly to a colder climate—the ratio of mortality, and the permanent loss of health, one year with another, would be reduced at least nearly one-half.

The work reflects great credit on the industry, talent, and learning of Dr. Bryson; and it cannot fail of being especially useful to those surgeons of the navy who may be stationed on the African coast, while the interesting facts which the volume develops will prove highly interesting to the whole profession.

TO CORRESPONDENTS.

THE MEDICAL TIMES may be procured by an order on any *newman* or *bookseller*, or it will be sent direct by post from the Office of the *Medical Times* to Subscribers sending by a *Post-office order*, directed *James Angerstein Carfrae*, or an order on some party in town, *One Guinea IN ADVANCE*, which will free them for twelve months. *Half-yearly Subscription*, 13s.; *Quarterly*, 6s. 6d.

An Army Surgeon of Forty Years' Standing writes us in reference to the branding of deserters:—"So *ne* five and thirty years ago my assistant was ordered to mark a deserter with the letter 'D,' not by the commanding officer, but by the officer in command. My assistant wrote to me for information on the subject. My reply was, that it was a dangerous affair to disobey an order, but if I were so ordered I should require time to learn the art of inflicting such a punishment; for such I considered it, not having acquired it in my medical studies, and I should be cautious in undertaking what I was totally ignorant of. This occasioned the desired delay. I wrote to the Medical Department and to the Commander-in-Chief (the Duke of York) on the subject. The reply was, no such order existed; and his Royal Highness's answer was, that he considered the duty should be performed by the drum-major, or his assistants, as other punishments, under the eye of the medical officer. Now, in these more enlightened times, if the army surgeons submit to so degrading an order it is their own fault, for a general memorial will instantly put a stop to it." We think the suggestions of our correspondent well worthy of consideration, and hope they will speedily be acted upon.

Dr. Edward Barry.—The patient was a private in the United States Army, wounded at the attack on Monterey. The man subsequently recovered.

Hippocrates.—Conia is both fluid and volatile. It is lighter than water, with a smell resembling hemlock. It is sparingly soluble in water, but imparts its odour and taste to it. Few poisons are more energetic than this. A single drop put into the eye of a rabbit killed it in ten minutes; three drops used in the same way killed a strong cat in a minute and a half; two grains, neutralized with hydrochloric acid, and injected into the femoral vein of a young dog, killed it in about three seconds. It is used in acute rheumatism and hooping-cough.

Adolescents.—There are many places where information may be obtained on the subject. A situation in town is rather difficult to be procured at first, as it is usually considered that a country and town practice differs considerably. An advertisement would probably procure what our correspondent wishes.

Sigma.—The prescription is evidently not the production of an educated practitioner, and what it is intended to accomplish we are unable to say.

M.R.C.S.L.—We believe that it is in contemplation to publish a new *Pharmacopœia*, but when the event will take place is better known to the College of Physicians than to ourselves.

Henfrey.—1. The regulations of the Company may be obtained by application to the secretary, at the Hall. 2. The Botanical Garden at Chelsea is open to students, under certain regulations. 3. The *Medical Times Almanac* contains a list of all the medical schools, hospitals, &c., in the Metropolis, with the fees which are paid.

Esculapius.—Dr. Mason Good's work is certainly an admirable one, and contains the most valuable information.

Mr. Alfred Ebsworth, Bulwell, Notts.—The communication has been received.

B., Reading.—We think confined to London.

An Old Subscriber.—1. The Apothecaries' Act is imperative; there must be an apprenticeship, or a party cannot be admitted to examination. 2. A party cannot recover for medical attendance unless a licentiate.

Medicus.—We do not trouble ourselves much about the burying-places of eminent medical men; we can gratify our correspondent, however, in reference to the illustrious Harvey. He lies in a vault in the church of Hemstead, a village in Essex, and access may always be obtained by paying a small fee to the clerk. His coffin, of lead, is in good preservation.

A Surgeon in the Country.—The entrance of air into veins is of rare occurrence, and the discovery of the circumstapace is comparatively of recent origin. Boyer denies that the spontaneous entrance of air into veins has ever proved fatal.

Celsus, Hull.—We generally append the name of the publisher to the books reviewed. The price of the work by D. Noble, entitled, "The Brain, and its Physiology," we do not know. Apply to Mr. Churchill, Prince's-street.

A. J. V., a Five Years' Subscriber.—We are so little acquainted with manuals intended for those who are about to pass Hall or College, that we are unable to recommend one, not knowing which is the best.

L. J. M., London.—Our correspondent has proposed to us a very difficult question, and one which we cannot answer. "What situation in London or its vicinity (say within ten miles) you would consider the best opening for a young man perfectly qualified, with moderate means, to commence as a general practitioner?"

A Young Country Practitioner.—Apply to Mr. E. Daniell, Newport-Pagnell.

Paralyticus.—We know nothing of the ten-guinea galvanic apparatus to which our correspondent refers. We would advise him to be cautious before he parts with his money.

M.R.C.S.E., Oxford.—The Company may not prosecute; but there is danger from any informer. By all means pass, in order to be safe.

Etzmon.—Our correspondent is facetious; we would advise him to write to M. Deschamps.

Amicus Certus.—The communication has been received, and the suggestions will be attended to.

We beg to apologise to Dr. Wright, of Birmingham, for the delay. It was unavoidable.

Letters and communications have been received from Dr. R. Grattan, Dunmore-house, Carbery, Ireland; Dr. S. Wright, Queen's College, Birmingham; Amicus Certus; Etzmon; M.R.C.S.E., Oxford; Paralyticus; A Young Country Practitioner; L. J. M., London; A. J. V., a Five Years' Subscriber; Celsus, Hull; A Surgeon in the Country; Medicus; Esculapius; M.R.C.S.E.; T. Henfrey; Sigma; Adolescents; Hippocrates; Dr. E. Barry; An Army Surgeon of Forty Years' Standing; F. A. Bulley, Esq.; Mr. Brown, Windsor; Dr. Bracebridge, Maybole; Dr. Gardner, Crieff; Dr. Robinson, Fintara.

THE MEDICAL TIMES.

SATURDAY, SEPTEMBER 4, 1847.

PUBLIC PHYSIOLOGY.—THE WOMAN OF FASHION.

To the thoughtful physiologist there is no more frequent subject of pity and sympathy than THE WOMAN OF FASHION. The sturdy beggar-girl—with her red cheeks and naked feet—enjoys perhaps a happier lot, physically as well as socially; Nature's worst-fated progeny being often better off than the most favoured child of society. And this is civilization!

The "fair favourite of fortune," as she is called, begins life amiss. The outset of existence sees her the "puling and puking" penalty, the screaming labour-curse of some workhouse drab, engaged to give her mother's milk and kindness to the worth of two shillings per diem. For the unspeakable joys of primal watching and worship from the parent pair, she has the specialised affection of a characterless mercenary, and thus, well-born, she atones, in the unremembered woes of infancy, for the too high breeding of her sire and dam!

As the oak in the acorn, so the woman in the babe; who, then, shall measure for us how much of that unloved infancy's history, unmarked in memory, has been left inscribed in her character?—how far alien unfeelingness on one side been mesmerized into permanent organization on the other; or, under that winter of stranger care, what leaflets of gentle emotion, what germs of human happiness have been nipped to death at once, or stunted to shapes of dwarfishness and deformity for ever!

But without running through, at a risk of tediousness, the consecutive influences which form and modify the ultimate organism, let us rather look at THE WOMAN OF FASHION as she offers herself to us on that eminence to which all her existence has tended, and thence seek to throw down light on the agencies of which she has been made the victim.

What, then, in the major cases have we? Measuring her by that very test by which she appraises everything—pleasure—the physiologist and the philosopher have only to take from her a companion, faithful as her shadow—that social mask which but adds to the pain it conceals—to find everything to pity, and nothing to envy. There is nothing true, or complete, or unquestionable about her, but her pains, her griefs, and her chagrins. Wretched without her "pleasures," she is unhappy in them. She has the waking moments of the opium-eater without his dreams—the tortures of a non-natural life without its enjoyments!

Why is this? Because we have here a false and bad condition of humanity; and with it, as by a law of nature, proportionate punishment. The "physique" is at fault, not less than the "moral"; and with them, in deep sympathy, suffers the intellectual. Nature, outraged by the worship of pleasure, vindicates herself by that very worship. She never designed the production of women of fashion and women of pleasure. It is against her ordinances that humanity should degenerate into an affair of rivalry and uselessness; and this has been so absolutely legislated for that the abuse exists only—and can exist only—through the perverted volitions of a still more perverted civilization. The pursuit of pleasure, as a profession, is the foolish invention of a luxurious age, and is, of its many foolish speculations, the most foolish and most unsuccessful. No extent of means and appliances can help the matter. Even the wealth and wisdom of Solomon leads there only to "vanity and vexation of spirit." It is a law of life that enjoyment go with duty and usefulness; and the way to make sure of happiness is to think of it in relation to others rather than to ourselves. Formed comprehensively—for the world without us, as for that within—no part of the great mechanism must be left to rust unused, or perish unexercised. With inactivity there is atrophy for the strongest muscle; with idleness there is disease for the healthiest

brain. If amusement be a *use*, a serious purpose is a necessity. Exclusive devotion to the levities of life, while an abnegation of the best portions of our constitution, a self-dethronement, and a self-desertion, is yet never pleasure. Pleasure exists not in the continuous indulgence of one propensity, or exercise of one faculty. The whole organism, with all its generous and self-denying impulses, requires to be brought into action; and there is as much real enjoyment in the sacrifice one association may suggest, as in the self-indulgence recommended by another. We have a framework which, though miraculously pliable and accommodating, will by no ingenuity allow us to be professional pleasure-hunters, except at the worst risks and highest penalties: Nature, in fact, has laid down the offence as capital. Happiness, health, life, are the sure punishments she exacts for it.

These are truths so obvious to medical men that to tell us of a "Woman of Fashion" is almost at once to point out to us a subject of nervous disease. Society is full of women made in this way physically unfit for the duties it expects from them; and who, as women, mothers, and citizens, are worse than useless to the world's progress. If we note the varied forms of hysteria, hypochondria, and lunacy—laughing and crying by turns, faintings, risings in the throat, difficult respiration, a demoniac sort of corporeal possession, extreme weakness and irritability of every organ, exaggerated sensibility, exalted imagination, unstable resolution and character, excitement, melancholy, *ennui*, *asthénie*, restlessness, spleen—such, the everyday phenomena of fashionable society, can be traced in clear sequence of cause and effect to the peculiar course of life that has been followed, and which has annihilated those qualities which give vigour to the muscles, or healthy energy to the brain. Their hours have been ill divided. Their midnights were passed in the excitement of an artificial day; their mornings in the enervation of a heated bed. Nature speaks in all ways, and with solar luminousness, against the abuse; but her protest is as ineffective as that of a peerage minority. Their food was ill chosen: it is tasking and depraving to the stomach, and stimulating to the organism. Their occupations have been bad: novel-reading, balls, theatres, and stimulating *réunions*; light, frivolous, exciting exercises, unhealthy to the brain and lungs—purposeless, unserious, and against the simple teachings of Hygiene and of Nature.

Thus women—the mothers of a new generation of Englishmen—go on in a time of high civilization: battling the laws of Nature, sapping their muscular strength and beauty: enfeebling the organs of respiration and nutrition, and putting irreparably out of order that beautiful nervous mechanism which alone can secure them the *mens sana in corpore sano*. By habit, system, plan—they go on producing as they best may, phthisis, hypochondriasis, hysteria, lunacy! And this is what the greatest wealth, the highest honours, and best means of information allow our highest born to accomplish for themselves amid the highest civilization of our nineteenth century!

It may be thought that these cases of feminine perversion of natural gifts are rarer than some of our expressions have indicated. It may be so in some instances: but in examples of less striking character the accusation extends even more widely than we have drawn it; and if the curtain were withdrawn, we should perhaps find

that we have understated both the intensity and the diffusiveness of the malady. In every public crisis that more or less comes home to the female bosom, how many cases—otherwise dormant—present themselves to the public eye of this species of feminine degeneration! It was among the fashionable women of Paris that were found those who successively, as Quietists, Jansenists, and followers of Mesmer, astonished the world by those odd phenomena which, associated with miracles by some, we know as results of nervous disease. In England we have had not dissimilar contagions (that of Irving's congregation being the most recent); and every day, to go to individuals, how frequently does the physician of high society meet persons who, like Pope's patient, "die of a rose in aromatic pain;" or, like the Duchesse mentioned by Reveillé Parise, complain that "the very wind from a person passing near them in winter suffices to give them catarrh;" or, like Anne of Austria, find swansdown too rough for comfortable usage; or, with the correspondent of Madame Sévigné, "feel sick at the mere sight of a good dinner!"

It is not, we need scarcely say, civilization that is in fault in all these, but a mistaken estimate of its elements and uses. The women of England are, in one view, too restricted by usage in their career of action; in another, they are ill informed as to the responsibility imposed on them by their organization. Human beings are not instruments of one string, like Paganini's violin. All their faculties, pechycal as physical, moral as intellectual, call for exercise, and, unless they have it, there is a broken harmony, and unmeaning and senseless discord. It is for medical men (as their privilege) to teach, as it is for the world (as their blessing) to receive, these truths.

SHIP FEVER.

THE remarks which we considered it our duty to make a fortnight ago in our columns, in reference to merchant passenger vessels, we are happy to say have produced a beneficial effect upon many of those individuals whose ships are engaged in conveying emigrants to distant parts of the world. At Liverpool the movement has commenced in the right direction, and the fashion is beginning to prevail of taking surgeons on board of emigrant vessels. Till the law becomes imperative, however, we must expect that the practice will not become universal, and it will be the duty of the Government, at an early period of the next session of Parliament, to adopt such measures as may appear likely to conduce to the health and safety of persons who are travellers by sea. It is a fact which is highly creditable to our country, that within the last few years the attention of the Lords of the Admiralty has been especially directed to the hygiene of the royal navy, experienced medical gentlemen have been consulted, and their suggestions in many instances acted upon, to the great benefit of officers and men. This department of reform is, however, yet in its infancy, but such a beginning has been made as will naturally lead to a code of regulations well adapted to remove most of those evils which spring from foul holds, deficient ventilation, and bad habits.

Public calamities oftentimes are the means of advancing the general good of a people, by directing their attention to the sources from which they spring, and calling into action those energies which prevent a recurrence of similar disasters. The ship fever, which has been

recently so destructive amongst the emigrants sailing to America, will open the eyes of the Government and public to abuses which have long existed in the mercantile navy. Under the fostering care of the demon of cupidity these have scattered disease and death amongst multitudes who have fallen victims, with scarcely a hand up-lifted for their help, or a voice raised to bewail their unhappy lot. If the waves of the ocean could speak they would tell of numbers committed to the deep, who on its bosom contracted diseases which were first produced by the neglect of those who ought to have been their guardians, and then proceeded unchecked to a fatal termination. If, as ancient saga taught, the manes of the departed sometimes required to be appeased, the spirits of innocent victims of mercantile cupidity are now calling from the billows of the Atlantic to avenge their wrongs, by the correction of evils which inflicted suffering and death upon them.

It is painful to contemplate the amount of mortality which has recently prevailed in emigrant ships: from calculations which have been made, and which have been as accurate as circumstances would permit, at least a fifth of the whole number have died. The symptoms which characterize the plague show that it is a malignant modification of typhus. Its first invasion is manifested by a rigor, speedily followed by great prostration of nervous energy, mental depression, and lassitude, while the conjunctiva exhibits the jaundiced hue which denotes a high state of congestion in the liver and impairment of its functions. In addition, there is oftentimes severe diarrhoea, bronchitis, and such profuse perspirations as to produce speedy prostration. Sometimes, also, about the sixth day petechiæ appear, which, with low delirium, or coma, announce the approach of death.

By an American journal we learn that, from returns made from the Montreal General Hospital, a fair criterion may be deduced of the average mortality of the ship fever, even under its most favourable chances of treatment. From the 28th of May to the 28th of June, 298 sick emigrants were admitted. Of these, 143 were cases of typhus, 18 were cases of diarrhoea, and 97 of common continued fever. The mortality among the typhus cases, every one of which was of the petechial type, was 1 to 4.9, or 20.4 per cent. Of the cases of simple continued fever and diarrhoea only one respectively died; while, estimating the mortality upon the general number of admissions, we find it to have been for the same period 1 to every 7.7 cases, or 12.9 per cent., the total admissions having been 324, and the deaths 42.

Now, we unhesitatingly affirm that this mortal disease did not get amongst the emigrants in consequence of contagion from Irish emigrants. If the position be assumed that it did, in order to shield certain parties from blame, it is one that is very weak, for if the disease had manifested itself in any one seeking a passage prior to embarkation, why take such a one? If it had not, and persons coming not from Ireland were first attacked, the sister country could not be the innocent cause of the frightful malady. From the facts which have come to our knowledge we can account for it in other ways. The vessels themselves, which are frequently chartered to convey emigrants to America, are oftentimes very improper receptacles for human beings for any length of time. Craft that have seen hard service for many years, and which are bought up for comparatively a small sum, are too frequently

employed. They are patched and painted for the occasion, and are made "mantraps," from which if victims escape when once caught, it is almost by miracle. The timbers are frequently rotten till almost decayed; the seams admit so much water as to require the frequent use of the pump to prevent too great an accumulation in the hold, while here there is such a mixture of sea-water with animal and vegetable substances in a state of decay, that the gaseous emanations, in spite of disinfecting agents, are too strong for one particular organ of sense to bear. Within the last three years vessels have put to sea in such a rickety condition that it has been declared by those competent of judging, that they must founder if anything like violent storms were experienced in the voyage.

We talk of foul drains and ill-constructed sewers, as being the prolific sources of disease in populous cities, but these are not more injurious to health than the filthy holds of crazy vessels crammed with human beings.

The food, also, with which emigrants are furnished is too frequently of a very inferior character. True it is that the Government requires a certain amount in good order to be shipped for each individual, but its authority is set at naught, and its officers are slow in discovering and exposing those infringements of law which justly deserve a severe punishment. Inferior food badly cooked cannot fail of increasing a liability to disease, when there are causes in operation to produce it, and of aggravating all the symptoms when once it is manifested in the constitution.

The steerage, moreover, is constructed in such a manner as to stow away the greatest number of human beings in the smallest space, without any regard to their comfort or health. Here men, women, and children are huddled together, in utter defiance of morality or decency: there is no classification of sex or age—no exercise of salutary authority by the captain or his officers: hence, there is often perpetrated the greatest excesses, and filth is sometimes allowed to accumulate to such an extent as to render it a matter of no small labour to pass to different parts of this region uncontaminated by the impurities. Such was the condition of some of the vessels in which fever recently prevailed; and it was actually necessary to lay down planks over the liquid filth and dirt in order to get to the passengers, who were too ill to leave their berths.

Here, then, we have causes which are adequate to the production of fever of the worst type, and it can be no matter of astonishment when it manifests itself. There can be no guarantee whether few or many individuals will suffer, or whether the disease will assume a malignant or mild character. As the owners of vessels have made such ample provision for the production of fever, it becomes a matter of serious inquiry, what provision have they made to check its progress when once it has appeared? We are compelled to answer, scarcely any. The law requires that every ship which carries one hundred persons or upwards on board, and every ship having fifty persons or upwards on board, the voyage of which is likely to exceed twelve weeks, shall carry as one of the complement some person duly authorised by law to practise in this kingdom as a physician, surgeon, or apothecary. But the greater part of the merchant navy does not come under the operation of this law, and another part which does, utterly disregards its provisions. Very few ships that leave our shores, except those belonging to the Govern-

ment, carry a surgeon; and if there are any owners who think it will entrap more passengers by announcing that a medical gentleman is engaged for a voyage, they seek for one who does not ask a salary for his services, only a free passage with the privilege of sitting at the captain's table. A free passage is fudge gratis, for the surgeon pays dearly enough by the service which he renders to those who may become sick. Little does the inexperienced professional imagine what a one-sided bargain he has struck when he engages to work his way over to the American shores. He must hold himself in readiness for service night and day, must set limbs when fractured, risk his life in the attendance of fever patients, be cooped up at night in a narrow and foul-smelling berth, and in the day sit at the captain's table in the character of a gentleman pauper. It is expecting too much of human nature for such a one to discharge his duties as cheerfully and efficiently as another who receives a fair reward and respectable treatment for his services.

Moreover, the evasion of the law by the mercantile navy in dispensing altogether with the services of properly-qualified medical men, or employing them without pay, acts most injuriously on the whole profession. It forces a number of young men to set up for themselves, who, if other fields of labour were opened up, with the prospect of fair remuneration, would enter upon them, and this would be one powerful means of doing away with much of that competition which reduces the price of professional labour and lowers the standard of medical respectability. No ship of any magnitude ought to be permitted to leave these shores without a surgeon on board, and, with such a law rigidly enforced, candidates would soon be able to demand a respectable remuneration for their duties, while many of the causes which are suffered now to exercise an uncontrolled influence in the production and perpetuation of fever would no longer exist. Merchants are secretly ashamed of their conduct in this respect, and it is only for the profession to watch them narrowly and expose their delinquencies to induce them to reform. At the same time Government should be memorialized, that any defect in existing laws which relate to the health of ships' crews and passengers may be remedied, and there will be then good reasons to hope that an effectual check will be put to the ravages of ship fever.

MORALS AND MEDICINE IN FRANCE.— CASE OF THE DUKE DE PRASLIN.

"Let me have
A dram of poison; such soon-speeding gear
As will disperse itself through all the veins,
That the life-weary taker may fall dead,
And that the trunk may be discharged of breath
As violently as hasty powder fired
Doth hurry from the fatal cannon's womb."

SHAKESPEARE.

THE murder of the Duchess of Praslin by her own husband, and his subsequent *felo de se* in the Prison of the Luxembourg, have excited the greatest interest not only throughout France, but also in our own country. A more barbarous act than that which hurried the deceased lady out of existence has never been perpetrated in any civilized nation, fifty wounds having been inflicted by the assassin on his victim, whose desperate struggles for life give an additional interest to the domestic tragedy. Articles of furniture were scattered about the floor. On different parts of the walls and doors were visible marks of a bloody hand. Portions of hair

were found adhering to the bed, and some of the same colour in the hand of the victim. Suspicion immediately falling upon the husband, he was put under close surveillance on the evening of the 18th, and the police never quitted him night or day. When on the following days he was closely examined, it was observed that there was a complete prostration of corporeal and mental energy, and, it having been surmised that he had taken poison, medical aid was sought to counteract its effects. The criminal so far recovered that he was removed to the Prison of the Luxembourg on the 21st, where he still continued to improve till the evening of the 23rd, when violent symptoms of a fresh character manifested themselves, and on the following afternoon, at five o'clock, he expired.

From the facts which have been published, we are enabled to conjecture that the Duke de Praslin took, on two different occasions, poison—the first at his own house on the evening of the 18th, shortly after the murder; the second on the 21st, in the prison, from the effects of which latter dose he died some eighteen or twenty hours after it was swallowed. There can be little doubt in the minds of scientific men that the first attempt at self-destruction was made by taking laudanum, the second by arsenic; but, in order to remove blame from certain high official persons, it has been diligently promulgated that the duke only swallowed one dose, composed of arsenic and laudanum, in his own house, shortly after the arrival of the police, from the effects of which he died some five or six days afterwards. In order to give plausibility to this statement, the *Journal des Débats* declared that, after the arrest, a phial was discovered in the pocket of the criminal's dressing-gown, which had contained a mixture of the two poisons just mentioned. It is an explanation, however, which the public will hardly receive, and which the profession will reject as not being substantiated by the symptoms which afterwards developed themselves.

It appears that the contents of three phials, discovered on the table, as well as that seized in the pocket of the dressing-gown, were analyzed by M. Chevalier, professor at the Ecole de Pharmacie. The result of this examination was, that two of the three phials taken from the table were found to contain laudanum, the third, nitric acid, and that which was delivered by the magistrate to the agent, contained a very small quantity of white arsenic mixed with laudanum, which had left in it a yellow tint. The contents of this latter bottle, the authorities would wish it to be believed, were swallowed by the accused. But let us look to the symptoms manifested, in order that we may draw our conclusions. In the first instance they were decidedly those produced by the taking of a narcotic poison, viz., prostration of strength, drowsiness, incoherent expressions, vomiting, and diarrhoea. The physicians were watching the effects of the narcotic, and they were made to say, through the medium of certain newspapers, that laudanum in an over dose never produces vomiting or diarrhoea! and that the symptoms of poisoning by arsenic are so little known that the most illustrious medical men may be mistaken in their diagnosis! The attendants on this occasion were MM. Orfila, Andral, and Louis, and they endeavoured to counteract the poison by the vigorous use of ice and wine! The patient unfortunately got better, when suddenly on the 23rd he was again seized with vomiting, which was now accompanied by the most excruciating sufferings, finished in a few hours by death.

Looking at the medical history of this case, we must say that it is utterly improbable that the criminal could have died with the symptoms which presented themselves from the first dose taken six days before, but that his death resulted from a large dose of arsenic taken a few hours previously. It has been diligently circulated, through the medium of the press, that laudanum never produces the symptoms which were first manifested in this case. If M. Orfila and his colleagues sanctioned the publication of this statement, they must have done so with the deliberate conviction that it was untrue, and thus permitted an indelible stain to rest upon their characters, merely to shield certain Government officers. The symptoms which appear from poisoning by laudanum are generally of a uniform character—giddiness, drowsiness, stupor. The expression of the countenance is ghastly pale. Not unfrequently there are vomiting and diarrhoea; and if these take place freely, before the more severe symptoms of narcotism set in, there is great hope of recovery. Nausea and vomiting frequently follow on recovery. Nature, therefore, assisted the Duke de Praslin to shake off the first dose, which was laudanum without arsenic, more than the doctors with their energetic doses of ice and wine.

It was evident by the 22nd that, if the criminal was to escape the hands of the public executioner, something more must be done, and under the very nose of M. Allard and his lynx-eyed agents, and in the Prison of the Luxembourg, another poison is taken—arsenic—which produced the wished-for result within twenty-four hours. The evacuation, on being analyzed by M. Chevalier, now gave unequivocal proofs of a large quantity of this deadly mineral being taken, and Dr. Rouget thereupon changed his treatment by administering to the patient certain emollients.

Now we admit, as some of the French papers have stated, that the effects of arsenic are known to vary in different persons; and that, while it often kills immediately, its fatal effects may sometimes be delayed for several days. When this is the case, however, there are not those anomalies which occurred in the case now under consideration. Large doses of arsenic usually prove fatal in from eighteen hours to three days; but the average time at which death takes place is generally about twenty-four hours. In the present instance there is no doubt the fatal results occurred within that period, whatever the members of the Government or the newspaper agents may say to the contrary. The culprit's suicide was willingly sanctioned by the officers of state, in order that a peer of France might not expiate his crimes by the scaffold, in sight of a taunting world. But what surprises us most is, that the first physicians of the kingdom should, with the eyes of Europe upon them, permit their honour and science to become prostrate before a proud aristocracy. Orfila, Andral, and Louis are stated to have been unable to form a correct diagnosis in a palpable case, and to have contented themselves with administering iced wines and simple emollients, when symptoms indicated the employment of the most energetic measures.

We deeply sympathize with the medical profession in France for this unfortunate occurrence; while we tremble for the fate of a great and powerful kingdom, when there are such indications of a low state of morals, which, if not corrected, must eventually be subversive of established institutions.

CORONERS AND MEDICAL WITNESSES.

[To the Editor of the Medical Times.]

SIR,—As I consider an act of injustice, involving a principle of impartial justice important to every medical man, has been done me this day under the following facts, may I request the favour of their insertion in your journal? Here they are, with all possible brevity, and the strictest adherence to truth:—

On Saturday last, about twenty minutes past four o'clock P.M., a person in a state of breathless haste desired me to run to Mr. Farley's, No. 5 in this street, as his servant had cut her throat. I lost not a moment's time in reaching the presence of the unhappy victim, whom I found dead, with her throat cut, and both carotid arteries divided. I was the first medical man who saw this state of things, and was full ten or fifteen minutes with the deceased, when the medical man, who attended her the day preceding, as he said, for a febrile attack accompanied with slight headache, arrived. Yesterday (Monday) I received a summons commanding me not to fail "at my peril" to attend the coroner's inquest, to be held at two o'clock this day, at the Ship, Little Tower-street. I accordingly attended. The second witness examined was the medical man above alluded to, who, deposed to what I have already stated. Upon this, Mr. Payne, the coroner, observed, my testimony was not required, my services could be dispensed with. I rose and stated that I was the first medical man who attended; that I was summoned to appear before him; and that I, therefore, felt I was entitled to my fee. I, moreover, added that I always understood it was his principle to give the fee to the medical man who first reached the spot, as a reward for his attention and activity in cases of such momentous emergency. This last observation I dwelt upon, because this very principle was enunciated by Mr. Payne himself to me in a conversation held between us both some two years ago, on our return from an inquest held within the Tower. This same principle I have never before seen trampled upon, though I have very many times given medical testimony before Mr. Payne. My case, however, was emphatically overruled, and that, too, in a spirit of unbecoming authority and marked want of urbanity.

Now, may I ask, on what principle of justice am I to be served with a peremptory command "at my peril" some twenty-four hours before hand to appear before him at a certain time and place, and not to receive any remuneration, save the indignity of an unenvied *dictum*, and the sneering mockery of an inquest-room?

Such peremptory commands may or may not be attended with the most serious inconvenience to me. On public grounds—on the grounds of "flat justitia, cælum ruat," towards the members of my profession—I address this letter to you, as my case is an illustration of unfair play, and demonstrative of a violated principle of justice: because, if I be wrong in this my condemnation, in all cases of sudden death, when perhaps half a dozen medical men hasten to the spot, the coroner may give the remuneration to any one he pleases, though the object of his preference might be the very last to deserve it.

I remain, your obedient servant,

WM. MAYLING, M.R.C.S.L. and L.A.C.L.
3, Little Tower-street, Aug. 31.

* POOR-LAW MEDICAL RELIEF.

[To the Editor of the Medical Times.]

SIR,—Nothing will contribute more towards the attainment of proper, adequate, and just remuneration to those who have the medical charge of large and extensive populations than the upholding constantly before the public the gross absurdities of the present system, carried on under the name of poor-law medical relief. I think it behoves every one who feels the burden of his position to raise his voice, and add a mite to the clamour against the iniquity perpetrated

on the poor, the community in general, and ourselves in particular. With this view, I proceed to represent to you my grievances, and I guarantee the correctness of my statements by privately forwarding to you my name, for I am unwilling to call down the wrathful indignation of those who have, at my own solicitation, confided in a large district to my care. In the remarks which I make, I do not blame the guardians at all: their duty is to give to the poor the rates in proportion to their immediate wants; their duty is to provide cheaply every article of necessity, and physics falls unfortunately amongst the items: the law and the commissioners are at fault.

Now, to my case. My district contains eight parishes; an acreage amounting to 14,000; a population of 8000, three-fourths of which are on the verge of pauperism from the long-continued depression in trade. To show to what an extent pauper medical orders are given, I may mention that my quarterly returns for the year ending the 25th of June, 1847, give 780 orders, and these, with about fifty, attended gratuitously, make 800 patients attended annually, and for what? the great sum of £60 per annum. The extensive range of the district compels me to keep one horse entirely for the service of the poor; now the lowest sum for which this can be kept is £20, and, £5 for wear and tear being allowed, one half of the salary alone is swallowed up. No one can supply the above number of paupers with proper medicaments and appliances under £30; I can most positively affirm, for I can prove from my bills, that such has been the cost to me for the relief, in leeches, medicines, &c., I have given. Thus, in one year, when reduced to figures, I calculate I lose £5 by giving my services to the Board of Guardians.

What is the amount of personal exertion this one year's work has cost me? I have ridden over not hundreds but thousands of miles, I calculate about 2700. Day and night has been all the same—a vast, distressed, dejected population, is my charge; their ailments are not to be lightly treated; a sacrifice of ease and comfort is necessary to the fulfilment of the duty properly—that sacrifice I have voluntary made, and, making it, I have gained, what?—a positive loss. Contrast my district with one not under the new poor-law—the parish of St. George's, Hanover-square—compare the salary of both, and we find there some approximation to justice towards the medical men: they receive £100 per annum each for the district, and £85 for the workhouse, and yet the paupers do not extend over a square mile, and in a year the number of cases seldom exceeds the number I have. Must not a manifest injustice exist in the medical relief granted by the poor-law commissioners, for they sanction the paltry pittance we get from boards of guardians? If a population, collected together in, as it were, a small compass, requires no more than the exertions of one person, without carriage or horse, to visit them in their diseases, it must be manifest that a country practitioner should have a salary far above the town one, because the expense of a horse must be incurred; and why should he be a loser, after devoting his time, his health, and comfort to the benefit of the poor? The more this subject is considered, the more we look into the circumstances of the case, the greater the unravelling it undergoes, the more do we feel the unequal burden with which we are burdened; and not until the whole system is rectified—not until equal justice is dealt out to the poor and the medical attendant equally—should we rest satisfied. A district like mine, and unfortunately there are numbers, should have a salary of at least £200 per annum attached to it, and the state ought to take this particular department to itself. The poets we all are honourable, but they have been made dishonourable to us; the high feelings we may possess when we canvass for the appointment are soon broken down by the thought that, do what we may, we cannot do well to the poor and ourselves too. The fault I find with the present state of things is, the discrepancy which exists between the

salaries of different medical officers. This week I see advertised a population of 3650, and small average, at £85, with extras. Now, for little more than half this sum I have to attend 8000, some of whom live seven miles from my residence. Can such things be without the keen-sighted commissioners taking immediate steps to rectify the absurdity? They have talked and talked of looking into this subject, year after year, but we see no result follow; each medical man is the patient ass—the load is on his back, they are careless to remove it from him. Our cry is not the cry of a mercenary class of men, eager to enrich themselves; we call aloud for the whole subject to be taken up by a commission and thoroughly investigated and placed upon a reasonable footing; we demand a salary which will pay for our horses, our drugs, our personal risk and danger, and we demand for the poor a more extended system of medical relief.

I remain, Sir, your obedient servant,
A POOR UNION SURGEON.

POOR-LAW RELIEF.

[To the Editor of the Medical Times.]

SIR,—On perusing your report of Aug. 28, of the coroner's inquest, held at the Holborn Union, I was forcibly impressed with the coroner's charge to the jury, as I feel very much instructed by it how to proceed in case of necessity, having the medical charge of an extensive union district, namely, the Woolton District of the Prescott Union. Mr. — (the coroner) observes, that the law empowers medical officers to administer to the sick whatever they may judge proper, at the cost of the union. A few weeks ago I was attending a poor man, and his wife and seven children, all ill of typhus fever; and on visiting them one evening I found them penniless, and in great distress and actual want, and not a morsel of any kind of food in the house. I was shocked at their destitution, and immediately procured them some mutton and rice, and oatmeal, to make some soup and gruel; and the next day, on making their destitution known, a subscription was quickly procured for their relief. A few days afterwards the relieving officer, who lives five miles off, came to the village, where he attends once a week, and I applied to him for the sum of 4s.—3s. for the food for this family, and 1s. for another man's removal. His reply was, that he would lay it before the board, which met the following day. He did so, with some observations of his own, as to its being an infringement of his duties; and the board have refused to allow the same, observing, I believe, that if I chose to turn relieving officer, I must do so at my own cost. This family, I again declare, were starving, and not a person to attend to them. Therefore, under these circumstances, I shall feel obliged by your insertion in your valuable publication, of which I am a constant reader, this most shameful fact, and at the same time, to say that I shall feel particularly obliged by your informing me how I must in future proceed, should I again be similarly situated. Perhaps you will favour me with the law. Am I, when I see poor objects starving and in want, to relieve them, and not have it returned? or am I to refuse them, and, in case they die, make myself, as the coroner observes, liable to a charge of manslaughter? The poor are hardly dealt with in this district (as well as in many others), to the great annoyance of the clergy, gentlemen, and ratepayers. I am, Sir, your most obliged,

J. ARMITAGE PEARSON, M.R.C.S.L.

Much Woolton, near Liverpool, Sept. 1.

* The inhumanity and injustice of the guardians is here placed beyond question; but Mr. Pearson in future cases may learn from this verdict that when his humanity extends beyond what the law provides for, he must consider himself as conferring private charity. Medical men at present have no legal duty in respect to such cases of destitution as he has described, except that of ordering the parochial authorities

to give that kind of medicine and sustenance the parties may require. The guardians disobey the order at their peril.—ED.

GENERAL MEDICAL ANNUITY FUND.

[To the Editor of the Medical Times.]

SIR,—The lamentable cases of Dr. Lynch of London, of Mr. Walker of Manchester, and of other members of the profession, latterly, induce me to bring before the notice of your readers the "General Medical Annuity Fund," established at Northampton in 1845. This fund was founded by Mr. Daniell, of Newport Pagnell, a gentleman well known to your readers by his numerous contributions on the subject; it is now regularly organized, under the presidency of Dr. Robertson, of Northampton, with trustees, directors, and numerous local secretaries in different parts of the country; and is receiving the cordial support of the profession. The object of the Institution is to provide annuities for superannuated or permanently disabled members of the medical profession, and for the widows and orphans of medical men.

The annual subscription is one guinea, and every one hundred subscribers will enable the directors to grant four annuities of twenty-five pounds each. It will be perceived that this society offers to each of its members the advantages of the benefit-society system, with the addition of an annuity to the widow or orphans after his decease.

It behoves every member of the profession to promote the benevolent objects of some such society as this one. Should his life and health be spared, he will by this means assist his less fortunate fellow-member; but should he be cut off in the midst of his career of usefulness, and before he shall have made provision for his family, his wife and children will not be left entirely destitute and dependent upon the sympathy of the public generally.

By allowing me thus very briefly to draw the attention of your readers to a society which promises to be particularly useful to our profession, you will oblige, Sir, your obedient servant,
T. HERBERT BARKER, M.B.

Bedford, Aug. 27.

DR. HICKMAN, THE ORIGINAL DISCOVERER OF INHALATION AS A MEANS OF PERFORMING PAINLESS OPERATIONS.

[To the Editor of the Medical Times.]

SIR,—In your letter of July 31 I remark an allusion to Dr. Hickman's invention, of performing operations under the influence of inhalation; and I am happy to observe that you appear to recognise the justice of his claim as the first inventor of the principle in question. You are right in your surmise, but he is no more. He died soon after this discovery, and before he had time to prosecute his inquiries. Had he still lived, I have no doubt he would have brought his experiments to a satisfactory conclusion.

I can put you in possession of a copy of the memorial which he addressed to the French King Charles X.; and I think, in justice to his memory, that his claim ought to be recognised by the scientific world. His widow is still living, and, as may be supposed, is most anxious for the claim of her late husband to be substantiated. Some time ago I addressed two letters to the *Lancet*, which were inserted in that publication, but no further notice has been taken of the matter.

The memorial is dated 1828, but I believe there are claims on behalf of parties prior to that period, but I know not on what evidence they are founded.

As a friend of Dr. Hickman's family, I have endeavoured to support his claim to this discovery—so far, at least, as the year 1828. As you appear to consider his claim to be founded on

justice, I trust you will use your influence to secure for the benefit of his widow any advantages that may result from the invention.

I am, yours,

THOMAS DUDLEY.

THE MEDICAL REPRESENTATIVE.

SIR CORONER,—I write to you neither in sorrow nor in anger. I am not going to be virtuously indignant. I am not even about to pity you. There are walking things, flying things, and crawling things. Why should I be angry with, or compassionate—either one or t'other? Every animal after its kind. Providence, no doubt, had some wise purpose in creating you, just as it had when it gave birth to caterpillars, earwigs, and other vermin. Therefore, Mr. Wakley, I am not about to blame you for what you said upon Finsbury hustings, touching literature and novelists. You no doubt spoke what you felt; and there is a natural deformity of mind, which it would be as cruel to attack as a natural deformity of body. If your soul be crooked and blind, I do not blame you. Heaven help us—you are as God made you. Any one of us might have been similarly afflicted—might have been born with a leper's hide, or a Wakley's feelings. And, therefore, Mr. Coronor, I merely mean to remark upon as a fact—not impute to you as a fault—your late notice of Mr. Warren and his books—and your general tone, when speaking of imaginative literature in general.

I am, Mr. Wakley, like yourself, an advocate of popular progress—unlike yourself, I am a real Liberal. And yet, when I read the sentiments you uttered, touching literature and literary men—when I remembered that the disgraceful words before me were spoken by a popular leader, and, worse still, when I heard of the burst of cheering with which a popular assembly received your vulgar diatribe—then, Mr. Wakley, I did feel how it was that so many great minds have held the masses in contempt. I did feel the force, the awful unhappy force of such words as the "rabble," the "unwashed," the "swinish multitude," and tried not to experience this feeling. I struggled to shut it out. I said to myself, the people are improving, schools are rising, institutes are springing up, there is good hope of a summer time coming—but even as I so murmured, the mental echo of the popular voice of Finsbury came ringing in my ears, and I felt—yes, felt in spite of myself—that such creatures as speaker and applauders were never meant by God to govern this—his world!

Oh, how often has my blood boiled when I read tales of popular sufferings—of feudal tyranny—of more modern persecutions—of the packed jury and the unjust judge. And these were wholesome feelings good to nurture and to cherish. 'Tis you, and such as you, who help to dispel them. If I despise you, how much more do I despise your disciples—& I pity the idol, how much more do I pity the worshippers. Yes, credit me, Mr. Wakley, there are hundreds of ingenuous minds opening and budding into fragrant thought—minds which worship at the shrine of imaginative genius as in the temple of a mighty God—minds, too, which would as naturally embrace the popular cause as the plants shoot upwards—but minds which, when they hear of such speeches as your late one, when they hear of the applause which followed it, will turn from the people, the masses, as a polluted and unwholesome thing—unworthy and incapable of being moulded by the hand of Genius into glorious proportions and exquisite outline, and fitted only to be dealt with by the coarse fingers of demagogues—to be fashioned into nauseous and corrupting forms—as ingenious but grovelling children love to make dirt pies.

Take care, Mr. Wakley. This is not your first escapade. Remember your estimate of Wordsworth. Not that in that instance you were so far from the truth—but the bias of your mind is evident—you despise art and literature. You think a brilliant novel beneath a clap-net

speech on a hustings. You rate the painter or the sculptor as inferior to the Brummagem patriot, who raves in the meeting about the parish pump.

These things hurt. These things damage the great cause of progression. I am one of its warmest if not of its loudest advocates. I would see the people governed by themselves—taxed by themselves—strong in themselves, relying on themselves. But to be liberal it is not necessary to be illiterate. To be a politician it is not necessary to talk of literature like a drunken colic-heaver. To win the confidence of a popular constituency, it is not, at least we trust so, requisite to show about as much appreciation of imaginative genius as one would look for in an Ojibbaway or a Bojesman. Not that you, Mr. Wakley, are one whit above the savages in this respect. But, as I said before, I say again, I do not blame you. I do not write this letter with any hope of reforming you, because I would not set up a manufactory intended to convert sows' ears into silk purses. But there is one thing you can and may do. You may be silent when you cannot be sensible. You cannot alter the brains which Heaven has given you—but you can hold the tongue—and thus prevent young minds from believing that a man may be a Radical, and yet a scholar and a gentleman—a conclusion at which the frequent perusal of your speeches would certainly prevent the most sanguine from arriving.

THE MAN IN THE MOON.

GOSSIP OF THE WEEK.

LONDON UNIVERSITY.

FACULTY OF MEDICINE.

The prizes for the summer term have lately been announced as follows:—

PATHOLOGICAL ANATOMY.

Professor Walshe, M.D.

Gold Medal and First Certificate.—Mr. William Filliter, of Wareham, Dorset.

BOTANY.

Professor Lindley, Ph. D.

Gold Medal and First Certificate.—Mr. Archibald P. Childs, of Bungay.

Silver Medal and Second Certificate.—Mr. William Bayldon, of Royston.

MEDICAL JURISPRUDENCE.

Professor Thomson, M.D.

Prize and First Certificate.—Mr. J. G. Thompson, of London.

The Fellowes Clinical Gold Medal has been awarded to Mr. S. F. Stratham, of Cranford, Middlesex.

QUEEN'S COLLEGE, BIRMINGHAM.

The annual meeting of the friends of Queen's College, in this town, was held August 25th, at the College. Lord Lytton, the Principal of the College, presided; and there were also present the Hon. and Rev. G. M. Yorke, C. N. Newdegate, Esq., M.P., J. E. Percy, Esq., George Attwood, Esq., Rev. G. S. Bull, Rev. J. Allport, Mr. E. T. Cox, Mr. E. Armfield, Dr. James Johnstone. Dr. Birt Davies, Aldermen Van Wart and Room, Mr. W. H. Osborn, Professors Knowles, Shaw, &c. Mr. W. S. Cox, the Dean of Faculty, read the report. The following students have obtained prizes:—

Junior Department.—Classics: Fryer, Colford.—Mathematics: Wall, Stratford-upon-Avon.—Chemistry: Edney, Kilmarnock.—Theological Prize: Fryer.—Mathematical Tutor's Prize: Fryer.—Medical Tutor's Prize: Fryer.

Special thanks are due to the examiners, the Rev. Wm. M. Lawson, M.A., and the Rev. W. B. Smith, M.A., who kindly assisted the Vice-Principal in the examinations of the junior department.

Senior Department.—Anatomy: Bird, London.—Surgery: Paterson, Stourbridge.—Medicine: Bird, London.—Materia Medica: Moore, Hales Owen.—Midwifery: Whittell, Leamington.—Lower.—Forensic Medicine: Whittell, Lane, Grosmont, Monmouth.—

Demonstrations: Hodges, Ludlow, and Bird, Esq.; Certificates to Brown and Barrett.

Thanks are especially due to Bramby Cooper, Esq., for the careful and satisfactory award made by him of the surgical prize.

NAVAL PROMOTIONS.—Assistant-Surgeon John McWhinnie (1838), to the rank of Surgeon.

NAVAL APPOINTMENTS.—Deputy Medical Inspectors: John G. Stewart, to Jamaica Hospital; Dr. James W. Johnston, to the Vindictive.—Surgeons: David Geddes, to the Poictiers; Dr. John Dunlop, to the San Jose; Dr. Charles O'Brien, to the Cambrian.

WAR-OFFICE, Aug. 27.—14th Regiment of Foot: Assistant-Surgeon William Lloyd has been allowed to resign his commission.—Hospital Staff: John Thomas Clarke, M.D., to be Assistant-Surg. to the Forces, vice Batley, appointed to the 5th Foot.

APOTHECARIES' HALL.—Gentlemen admitted members August 26: Thomas Morris Ward, Patrick Downey, William Hand, George Alfred Rhodes, Sherand Freeman Statham, and William Emerson.

UNIVERSITY COLLEGE, OXFORD.—By the decease of George Joseph Bell, M.B., of this college, who died on his way from Persia in May last, one of Dr. Radcliffe's Travelling Fellowships is now vacant. Mr. Bell was elected in 1842, and the fellowship is held for ten years. Dr. Radcliffe, by his will, charged his estate in Yorkshire with the payment of £600 per annum to "two persons," to be chosen out of the University of Oxford, when they are masters of arts, and entered on the physic line, for the maintenance of the said two persons, for the space of ten years, and no longer, the half of which time at least they are to travel in parts beyond the sea, for their better improvement." Chambers are assigned in University College to the two Fellows. The electors are the Archbishop of Canterbury, the Lord Chancellor, the Chancellor of the University, the Bishops of London and Winchester, the two Principal Secretaries of State, the two Chief Justices, and the Master of the Rolls, or the major part of them.

DANGERS OF MEDICAL MEN IN THE FIELD OF BATTLE.—"On the morning of the 21st," says Dr. Jarvis, United States army, "the whole division was thrown forward towards the city, with a view, as we supposed at the time, of making a diversion in favour of the 2nd division, under General Worth, which was moving on the western side of the city by the Saltillo road. Few of us supposed, as we silently marched along, occasionally passing through corn fields, and by the side of hedges, or whatever could conceal our movements from the enemy in their batteries, that we should so shortly be engaged in a fierce and deadly strife. As soon as, or in fact before, we emerged from under cover, the batteries from either end of the city opened their fire upon us, completely sweeping the plain in every direction, and enflading the advancing columns of our troops, now rapidly marching towards the suburbs. The engineer officer having reported the practicability of attacking with success the rear of some of their forts, the 1st, 3rd, and 4th Infantry were ordered to advance rapidly by separate roads; and now it was my professional labours commenced. The nearest and only shelter that presented itself to me for the wounded, falling every moment under a most destructive fire, was a quarry pit, four or five feet in depth, and the same in breadth. Several of these were contiguous, and to them I directed the wounded to be carried. By stooping we were protected from the shots, which, however, became every moment thicker, owing to the fact that our troops had by this time advanced within range of the enemy's fire, and the moment they perceived a party of men bringing the wounded to us, they directed all their guns upon it. I had already performed one amputation, and was preparing for a second, when two or three fugitives rushed into the pit, falling over the wounded that lay there crowded together, saying that a large body of lancers were approaching.

No little credit did I attach to their report, which I ascribed rather to their fears than the actual presence of this dreadful description of troops; that I never raised my eyes to observe them; which circumstances doubtless saved us all. Had I been discovered, all would have been sacrificed, as, in their headlong fury, they would neither have delayed to ascertain our character or profession, nor have paid much respect to our patients. Several soldiers who had sought an adjoining pit with an officer were slain. They were soon after repulsed by a regiment of Ohio and Mississippi volunteers, marching to reinforce those already in the town, and their retreat was further quickened by a shower of grape opened upon them by our artillery.

Desirous of seeing a correct Medical Directory, we readily accede to the wish of the editor, and direct the attention of our readers to the advertisement on our wrapper, which promises great improvements in this important annual. The spirit and energy of its proprietor should be responded to. There will be little need of reviving the question of the Medical Registration Bill, and disturbing, to no purpose, the profession to its centre, if this book becomes what it professes to be and ought to be.

MR. G. HUXLEY'S CAOUTCHOUC STOCKING.—This is another of those mechanical inventions to which surgery is so much indebted. The adaptation of india-rubber to the purposes of compression for varicose veins, &c., is correct in principle, and the form which the principle here takes is more than unexceptionable: it is admirable. For the equal diffusion and permanent maintenance of pressure we have seen nothing which with more pleasure we can recommend to professional cognizance than the invention submitted to us by Mr. Huxley.

OBITUARY.—On the 26th inst., at Oxford, deeply regretted, John Wootton, Esq., M.D., of Balliol College, and one of the physicians of the Radcliffe Infirmary, in the 48th year of his age.—On the 1st inst., in Gloucester-place, after a long and painful illness, Sir Richard Dobson, M.D., F.R.S., &c., Inspector of Hospitals and Fleets, aged 74.

MORTALITY TABLE.

For the Week ending Saturday, August 28, 1847.

Causes of Death.	Total.	Average of 8 Summers.
ALL CAUSES.....	1084	940
SPECIFIED CAUSES...	1082	935
Zymotic (or Epidemic, Endemic, and Contagious) Diseases.....	366	226
SPORADIC DISEASES.		
Dropsy, Cancer, and other Diseases of uncertain or variable Seat.....	135	108
Diseases of the Brain, Spinal Marrow, Nerves, and Senses.....	134	157
Diseases of the Lungs, and of the other Organs of Respiration....	195	226
Diseases of the Heart and Blood-vessels.....	30	25
Diseases of the Stomach, Liver, and other organs of Digestion.....	106	94
Diseases of the Kidneys, &c. Childbirth, Diseases of the Uterus, &c.	8	8
Rheumatism, Diseases of the Bones, Joints, &c. ...	15	10
Diseases of the Skin, Cellular Tissue, &c.	10	7
Old Age.....	2	2
Violence, Privation, Cold, and Intemperance.....	55	50

SUGGESTIONS

FOR A MORE SIMPLE ARRANGEMENT OF THE

MATERIA MEDICA,

BASED ON ITS PHARMACEUTICAL AND THERAPEUTICAL RELATIONS.

By GEORGE LEITH ROUPELL, M.D.

Cantab., F.R.S., Fellow of the Royal College of Physicians, Physician to St. Bartholomew's Hospital, Lecturer on *Materia Medica* at the College of St. Bartholomew's Hospital.

(Continued from p. 524.)

LECTURE VIII.

I here to-day briefly glance at the second class of bitters, which is composed of such as are amorphous in shape, or not, at any rate, regularly crystalline: these are absinthine, cetrarine, lupuline, lactucine, pareirine, and cathartine.

25. Absinthine is the bitter principle of the *artemisia absinthium*. The botanical name absinthium, and the trivial one of this plant, wormwood, are expressive of some of its qualities and supposed effects—the one being indicative of the nauseousness of its taste, and the other of its efficacy as a vermifuge.

Wormwood is powerfully tonic, to some extent febrifugal and anthelmintic. It is now comparatively rarely used, though formerly a remedy of great celebrity. It has long been famous as a corrective of dyspepsia, especially of that form which is induced by habits of intemperance; and there is no question of its utility in hypochondriasis, hysteria, and debility. Haller tells us that in his own case he found it efficacious when labouring under gout.

The flesh and secretions of animals fed upon wormwood acquire its bitter taste.

26. Cetrarine is described by M. Herberger as a white powder like magnesia, undergoing no change on exposure to the air; inodorous, but of a strong bitter taste; little soluble in water, hot or cold, but readily soluble in alcohol, ether, and alkalis. This is the active medicinal principle of the *cetraria islandica*, which is a useful tonic in cases of debility, and is especially indicated when accompanied by emaciation, as, besides cetrarine, it contains a nutritive principle—starch.

Dr. Müller found cetrarine an effectual remedy in ague when exhibited in doses of two or three grains.

27. Lupuline, or rather lupulite, is the bitter principle of the hop. It appears in the form of a yellow, uncrystallizable matter, neutral in its reaction; slightly soluble in water, more readily in alcohol.

A very useful combination of properties is found in the hop, which is tonic, aromatic, and, in the opinion of the public, narcotic.

An infusion, a tincture, and an extract are the official preparations.

28. Lactucine is the entire bitter principle of the lettuce. It is neutral, and obscurely crystalline.

The lettuce is calmative and anodyne, and may

advantageously be exhibited when other sedatives disagree or produce unpleasant effects.

The official preparation, the extract, if carefully made, is a good form for its exhibition.

29. Pareirine. Under this head I shall treat of the *cissampelos pareira*, applying this term to the yellow bitter matter with which the crystallizable substance *cissampeline* is combined. *Pareira brava*, introduced into practice as a cure for calculus, is decidedly serviceable in some cases of irritation of the mucous membrane of the bladder. It appears almost a specific for such forms of inflammation of that viscus as are characterized by copious discharges of aropy secretion.

The infusion and extract of *pareira* are the formulae at present in use. A stronger decoction is, however, required.

30. Cathartine, discovered by M. Lassaigne in the leaves, and by M. Feneulle in the pods, of the senna plant, is a red, uncrystallizable, non-azotized substance, of a bitter and nauseous taste. It is the efficient portion of the senna, proving actively purgative (and not without griping, according to the experience of M. Feneulle) in doses of two or three grains. Cathartine is soluble in water and alcohol, but not in ether.

Senna, the produce of different varieties of *cassia*, is the most certain of our purgatives, stimulating rather than depressing the system. Its preparations are the compound infusion, the compound mixture, the confection, and the syrup.

III. Bitter Principle in the Form of Extract. In this division several drugs will be treated of the active principle of which is yet doubtful. In some it exists no doubt, variously combined, chemistry having yet failed to exhibit it to us in a distinct and separate form. As good an example of this order as can be found is—

31. Aloesin. This is a reddish-brown substance, translucent in thin layers, soluble in water and weak spirit, insoluble in alcohol and ether, intensely bitter to the taste, and actively cathartic in its effects. It exists in the proportion of from 50 to 80 per cent. in the various descriptions of aloes.

Aloes is a bitter tonic and an aperient. Its laxative effect is chiefly occasioned by its stimulating the large intestines, the explanation of which peculiarity has recently been sought in the solvent property of the secretion from this portion of the alimentary canal.

The official preparations of aloes are numerous, the empirical ones endless. It is one of the best means of obviating the tendency to constipation, as it acts simply by increasing the peristaltic movement of the intestines. It is the best substitute for bile when deficient, as it more resembles bile than any other known substance.

Its well-known tendency to irritate the rectum and neighbouring parts has led to its employment as an emmenagogue, and its prohibition in cases of hemorrhoids or in pregnancy.

An extract, three formulae for pills, a wine, a decoction, a simple and a compound tincture, are preparations of aloes to be found in the London Pharmacopoeia.

32. Colocyathine is a pale yellow matter, brittle, transparent, soluble in water and alcohol, intensely bitter, and violently cathartic. It exists in the proportion of fourteen per cent. in colocyath, and is its efficient portion. Colocyath itself is rarely used, but the simple and compound extract form our ordinary aperient pills, a mode of exhibition especially suited to this drug from its extreme bitterness.

33. Rhamnine appears in various forms, according to M. Henry—in light scales or small grains, or even in arborescent crystallizations. It is of a yellow colour, of a bitter taste, though not very strongly marked.

Rhamnine is the active principle of the *rhamnus catharticus*, the berries of which are powerfully cathartic. The fresh juice boiled with ginger and pimenta berries, with the addition of sugar, forms the syrup of buckthorn, an old and efficient remedy for dropsy, though one which has yielded to other hydragogues less apt to produce nausea and griping.

34. Taraxacine must be classed amongst neutral, non-azotized substances, and is bitter, with some acidity. According to M. Pollex, it appears in the form of stellated crystals.

Taraxacum is useful in hepatic obstruction, acting as a diuretic and gentle aperient; it is supposed to increase the secretion of bile.

It is most commonly employed in the form of an extract.

35. Diosmine is the bitter extractive matter which, in combination with the essential oil of bucku, renders it a valuable remedy in urinary diseases. It acts as a tonic, diuretic, and stimulant, checking the secretion of mucus poured out from the membranes when in a state of chronic inflammation, and allaying excessive irritability of the bladder.

36. Ergotine. This principle, discovered in the spurred rye by M. Wiggers, is thought by him to be the active principle of the secale cornutum. He describes it as narcotic and poisonous, appearing as a brown powder, bitter to the taste. M. Bonjean thinks it, when loosely applied, a very powerful styptic; and, when taken internally, he has always found it successful in uterine hemorrhage.

The chief use of the ergot of rye is to promote the contraction of the uterus either before or after delivery, and to restrain hemorrhage from various parts.

The powder is generally employed.

37. Serpentinine is the bitter extractive matter of the serpentary, to which, with an essential oil, its efficacy is to be referred.

Serpentary is tonic, diaphoretic, and stimulant; hence is useful in the advanced periods of low fever.

The tincture and the infusion are the official preparations.

38. Cascarrilline is the last of this order to which I shall allude.

It is not yet decided whether or no cascarrilla contains an alkaloid for the present we must consider its bitter extractive matter, with its acrid resin and essential oil, as together constituting the efficient components of this bark.

Cascarrilla, from the combination of aromatic with tonic properties, is useful in some forms of dyspepsia, in chronic diarrhoea, and dysentery. On the Continent it is esteemed as a febrifuge, and it may be, at any rate, usefully combined with cinchona when that remedy disturbs the stomach.

An infusion, a tincture, and a mixture, are directed to be prepared by the Pharmacopœia.

Neither time nor space permit me to dilate further on this class of drugs: it is one which will obviously require much modification, and is one which calls for additional researches on the part as well of the analytic chemist as of the medical practitioner and physiologist.

CLINICAL OBSERVATIONS ON SOME OF THE MORE FREQUENT DISEASES OF CHILDREN.

By W. HUGHES WILLSHIRE, M.D. (Edin.), M.B.S., Physician to the Royal Infirmary for Children, &c.

(Continued from p. 505.)

To-day, gentlemen, I shall conclude what I have to say upon the treatment of *tuberculous meningitis*.

In the first place I shall read you the notes of one or two cases which will illustrate both the utility and inutility of the practice I recommended you to follow in endeavouring to arrest the progress of this very fatal disease.

The first is a case in which the disease was arrested after some stupor had supervened.

Dec. 9, 1845.—Richard Vere, of Christchurch, in his eighth month, is attacked with vomiting and constipation; his brow is knitted, and he sleeps very much. His mother says, "the head hangs about, and he is very heavy;" his face is pale, fontanelle tense and convex; he is scrofulous-looking. Tuberculous meningitis is to be feared.

Ordered to have his head shaved, and a blister placed upon the scalp, a mustard cataplasm between the shoulder blades; castor-oil 3i., oil of turpentine 3ij., to be injected. To be placed up to the chest in warm water.

10. His mother states that soon after I saw him he passed into a state of stupor, but has been much relieved since the applications and injections were resorted to. Bowels relieved four times. There is much heaviness; breathing rather laborious; nervous system oppressed; pupils contracted. Ordered a blister behind each ear, and repetitions of mustard poultices to nape of neck. Repeat the injections, increasing the turpentine by 3j.

11. Decidedly better; bowels relieved three times; breathing yet laborious, but not so much as yesterday; blister discharging. Ordered

to repeat the mustard poultices to neck, to take four grains of cathartic powder, and have the injections repeated.

12. Head symptoms very greatly relieved, and blisters behind the ears well open. Ordered to have the injections repeated, and 3ij. of the following mixture every two hours:—Sodæ desquicarb, 3ss.; aquæ carui, 3ij. M. To have the iodine ointment applied to the head.

14. Head symptoms gone; tongue rather foul; motions very pale. Ordered mercury with chalk gr. j., soda gr. viij., at bedtime; and chlorate of potash gr. iij., infusion of gentian 3ss., every three hours, mixed with a small quantity of sugar.

January. Discharged convalescent.

The next is a fatal case. June 23, 1844. David Perryman, Lambeth, in his thirteenth month, is attacked with vomiting and constipation. The fontanelle is tense, and the head seems heavy to the child, although it is comparatively lively. Child strumous-looking, small, and delicate; mother strumous; her first child; tuberculous meningitis is to be feared. Ordered to have the head shaved and the comp. iodine ointment applied; a blister behind each ear; aloes and sulphate of potash, each two grains, directly; an hour after, two drachms of castor-oil, to be repeated every three hours until the bowels are relieved.

24. Liveliness gone; child dull and heavy; sleeps much; face warm, but pale; bowels have been relieved; case altogether much worse. Ordered to have the powders and oil repeated as before, a blister to the nape of the neck for four hours, and afterwards a poultice. To take iodide of potash gr. ij., iodine gr. 1-10th, distilled water 3ij., every two hours, mixed with sugar at the time of taking it.

25. Stupor, but the child can be roused, and when aroused swallows; bowels not relieved. Case worse. Ordered, powder of elaterium gr. 1-16th, sugar gr. iij., directly. If need be, castor-oil to be given in the evening. Repeat the iodine mixture.

26. Has been better since the elaterium operated well. Ordered to have the elaterium as before. Go on with the iodine.

27. Has relapsed again, and is now much worse; lies mostly in a calm stupor, but now and then grinds the teeth, and moves about his arms; the mother says he has been slightly convulsed. Ordered to have the elaterium and mixture of iodine as before. To have the whole scalp blistered.

28. Took the powder, but could not be got to swallow the mixture. The mother refused to have the head blistered. Bowels have been well moved; child breathing unequally, irregularly; lies constantly on its back; eyes begin to be gluey. Case much worse. Told the parent it was dying.

29. Cold all over except the chest; dying.

30. Died half an hour after I last saw it.

Post-mortem.—A tuberculous cyst exists, the inferior part of which is imbedded in the superficies of lower part of left hemisphere, uniting, as it were, membranes, brain, and skull altogether by adhesions at that point. The outer wall, as it may be called, of the cyst forming adhesions with the membranes, and these again being strongly adherent to the inner wall of skull. Another cyst exists between the pons and cerebellum. The membranes at the base inflamed; granular deposition of tuberculous matter there. Slight effusion into the ventricles; no softening of central parts.

The next is a very interesting case, and formed the basis of a discussion one night at the London Medical Society.

Mary Shanks, aged ten years, nearly two weeks ago complained to her mother of pain in her head, especially when at school. The girl getting worse, unable to be sent to school, and the bowels being rather relaxed, advice was sought; the patient was said to have fever, but which would soon be better, and was ordered "fever medicine." The treatment was continued for a week, but at the end of it, as the child

did not improve, she was brought to me at the infirmary. She now presents the following symptoms:—Complains of great pain at the top of the head, which is often intense; pain also along the neck, at epigastrium and at the left side. She is constantly sighing; her hands hang listlessly at her side; every now and then she is taken with great trembling; is thirsty; there has been vomiting; the bowels are now constipated, and the tongue is very foul. The cutaneous capillary development is very great, and the child is emaciated. She seems low; the pulse is feeble; speaks in a sort of moaning tone, interrupted by the tremors which frequently come on. Ordered to have the head shaved directly, a blister placed behind each ear, and to be dry-cupped at the nape; to have the comp. iodine ointment rubbed over the scalp night and morning; to have eight grains of aloes and four of sulphate of potash night and morning; one-fifth of a grain of iodine, two grains of the iodide of potash, every four hours.

17. Child worse; in bed; all the signs of brain affection increasing, the pain and tremor being very great. Ordered to continue as before. Apply a blister to the nape of the neck.

For three or four days the child seemed truly much better, but on the 21st the fever increased, and she was ordered the blisters behind the ears, and the following:—

R. Potass nitrat, gr. v.; ant. pot. tart., 1-12th; liq. ammon. acet., 3ij.; mist. camph., 3vj.; 4ta quaque hora.

The child remained much in the same way until the 23rd, when the following is my note to the house-surgeon upon her paper—Rept. ut xxj.:—"Dear Sir, be so good as to see this patient this afternoon, and if coma has supervened blister the scalp; I am rather at fault this morning: I cannot clearly make out whether the child is only very sleepy, or that coma is foreshadowed."

It was not thought necessary, however, to alter the treatment or apply the blister until the 26th, when it did not rise, on the 27th another was applied which rose well, and the patient again rallied. A cathartic powder and the saline mixture just mentioned were continued.

29. Complete coma has supervened; pupils dilated; ordered to have the scalp dressed with the tart. antim. ointment. Injections of turpentine and castor-oil to be given.

31. Child getting worse. Injections not given by the mother, who substituted castor-oil by the mouth.

Little was done after this; in two or three days the child died. I may remark that this child was the tenth who had died out of a family of fifteen; and that the father was then subject to epilepsy.

Post-mortem Twenty-four Hours after Death.—Skull unsymmetrically developed; slight congestion of veins and sinuses of dura mater; very evident flattening of convolutions, and raising of sulci; on pressure the brain seems very firm. Along the edges of the convexities of the hemispheres is lymph deposited, with numerous yellow granulations. In one or two places the hemispheres adhere by the falx. No increased vascularity or congestion of the arachnoid, &c., or of the cerebral substance itself. In the white substance of each hemisphere is a cretaceous mass, about the size of a pea, apparently the cretaceous state of tubercle. Ventricles much distended by about 85 of fluid; no softening of central parts. At the base of the brain, from the junction of the medulla with the pons to the commissure of the optic nerves, is a great amount of gelatiniform exudation, and at one spot many yellow granules.

The points in this case to which I would direct your attention are the following:—The liability to have mistaken this case at its commencement for simple fever; even when I first saw it, had it not been for the great trembling and sighing respiration I should have so regarded it. The headache being at the vertex and not frontal. In the agreement of the fact of relaxation of the bowels being put an end to by the super-

vention of the meningitis, with the like fact observed by Gerhard, Plet, and Green. The peculiar trembling and sighing, &c., just alluded to. In the agreement with the observation of Rilliet and Barthes, that tubercles of the brain are more frequently met with in the hemispheres, and that gelatiniform serosity is more common at the base. Lastly, the inutility of any kind of treatment in such a case, though at the same time proving the value of the severe counter-irritation in temporarily rousing the vital powers.

I told you I should make a few observations before concluding the subject upon the different methods of treatment advised by others. This I shall now do, because, in relation to so important a malady, it is but right you should be acquainted with the different kinds of weapons which have been used against the disease.

Of the purely *antiphlogistic* plan I need say little, for you will have learned that it is not applicable to our present disorder, and experience proves this, since, although it has been vigorously employed in all stages of the malady, it has no effect in warding off the fatal termination, on the contrary, in many instances it will hasten the event. Although, then, we cannot hope, like Dr. Maxwell, to cure sixty out of ninety cases of acute hydrocephalus by placing the child in the horizontal position, opening the jugular vein, and continuing the bleeding until the pulse is imperceptible, yet we may hope to relieve somewhat the local congestion or increased vascular action which so frequently accompanies the early periods of the malady by applying a few leeches behind the ears, or cupping at the neck, as I have told you, and, therefore, need not dilate more upon the point here, simply enforcing on your attention the fact that in tuberculous meningitis the inflammatory action, when present, is not of that description which is *materially* benefited by the loss of the circulating fluid, however, and to what extent, it may be brought about.

In Mr. Field's "Veterinary Records" you will find two cases of hydrocephalus, related as occurring in the horse, and which, on dissection, showed the ventricles distended with water, &c. These horses were freely bled, and rapidly became worse, and died. Mr. Field remarks that "an animal, under such circumstances, cannot bear the loss of blood, extreme restlessness, &c., supervening."

With respect to the *mercurial* plan, I might say a little more in its favour, and others you will find who place great hopes upon it. But even here all that I look for, is the value of the mercurials exhibited in producing continued action on the bowels, and exciting more biliary secretion from the liver. As to the specific power of mercury in stopping the progress of the disorder I have no belief, or in its supposed virtue of hindering the ventricular effusion, as is rested upon by some. Many in this disease have given enormous quantities of calomel: one case is on record in which 310 grains were given, and an abundant salivation was produced, and the child is said to have recovered. Dressing the blistered surfaces with the mercurial ointment along with the internal exhibition of some one or other form of the metal has commonly been adopted. You will find that many of the cases of averted recovery from acute hydrocephalus have been treated by this plan; and, says Dr. Bennett, "weighty and varied testimony in favour of calomel might be adduced from numerous authors who have written especially on this subject, from Dr. Dobson down to the present day."

The next general plan which has been by some adopted is that of powerful and constant *purgation*, and I am myself inclined to lean to it more than to any other, when adopted in combination with counter-irritation. I think Rilliet and Barthes do not bestow by any means the credit upon this method which it deserves. Whytt and Rush strongly recommended it, Abercrombie gave croton oil, and Clutterbuck and Elliotson elaterium. The latter I have administered myself. I prefer, however, keeping up purgation by means of aloes and sulphate of potash, and injections of castor and turpentine oils.

Of counter-irritation and derivation by means of mustard cataplasms, blisters, and dry cupping, &c., I have a high opinion—so far, at least, as I can have in this disease of anything applied as a means of cure. Many persons of repute have recommended them, often differing, however, where and when they should be employed. Some blister the scalp, others the neck, or the mastoid processes; whilst others advise the epigastrium or lower extremities to be attacked. "Hot-water moxas" on the posterior portion of the nape, and the common moxa to the occiput and behind the ears, have also been recommended. Myself, I prefer, on the whole, blistering behind the ears, and repeating mustard poultices to the nape of the neck, whilst iodine ointment is applied to the shaven scalp, and pediluvia of hot water containing salt or mustard are had recourse to in the earlier stages of the malady; afterwards a blister to the whole scalp, kept open by an irritating ointment.

Some have given largely *narcotics* and *sedatives*; and a few agents, like digitalis and opium, have received high encomiums, especially the former. I must refer you to Dr. Bennett's book for information upon this method, however, as I know nothing about it myself, never having witnessed any one symptom, viewed in relation to the generally observed *post-mortem* appearances met with in this disorder, which appeared to authorize me in adopting it. Yet it has great names in its favour.

I advised you, you will recollect, to give *iodine* internally, and use it externally as well; and you must know that this agent has lately been very strongly recommended both by some of us and the continental practitioners. I am disposed to place much more reliance on it than on mercury, viewed as a specific agent in controlling scrofulous inflammation and its effects; as, also, over those aberrations of simple nutrition so characteristic of the scrofulous constitution, and which I have already fully touched upon, it has more power than anything else. In practice, I have seen decided benefit from its use. With regard to its mode, administration, &c., I have spoken to you before. Some few have more strongly recommended the combination of iodine with mercury in the form both of the proto and deuto-ioduret of mercury, and each has been said to have produced cures. I gave the latter in two cases which proved fatal. I followed the formula quoted by Bennett from Schmidt's "Jahrbücher":—

R. Calomel, gr. viij.; iodini, gr. j.; sacchari albi, gr. lxxx.; M. fiat pulv. et divide in partes xvj. æquales. Sumat j. 4ta quaque hora.

In preparing the deuto-ioduret, the calomel should be first rubbed with the iodine, and afterwards with the sugar.

Excitants and cordials have been rightly recommended in the later stages of the disorder, and I have seen a temporary rousing of the powers from their use; but at this period, whatever is done, the child always dies.

Certain special agents or *empirical* means have been, of course, recommended—such as musk, oxide of zinc, phosphorus, and quina. Nor has the tincture of cantharides been forgotten, or colchicum, or enemas of tobacco!

ON THE PHYSICAL PHENOMENA OF LIVING BODIES.

By Professor MATTEUCCI, of Pisa.

PART XIV.

MUSCULAR CONTRACTION—ANIMAL MECHANISM.

Muscular contraction, and the locomotion resulting from it, are effects of the nervous force.

The will—mechanical actions—heat—electricity—determine muscular contraction by their action upon the nerves; the integrity of the nerves is indispensable to produce this effect. It is evident that a force (the nervous force) travels along the nervous filament, and arrives thus at the muscular fibre. On the other hand, we are obliged to admit that this fibre possesses the property of contracting under the action of the

nervous force; and we can hardly account for the strange pertinacity with which physiologists have so long insisted, and continue still to insist, upon the correctness of certain exclusive theories which would ascribe muscular contraction to the action of the nervous force alone, denying the contractile property of the muscular fibres, or to the latter independently of the nervous force. The velocity with which the nervous force is propagated is undoubtedly very great, and may be compared to that of light and electricity. We must, however, without denying the correctness of the latter supposition, observe that experiments in support of it are still wanting: the distances which the nervous force has to traverse are exceedingly short, and we need not be so very much surprised, therefore, at the velocity with which it travels. If we observe a muscle at the moment of its contraction, we perceive that its longitudinal fibres are shortened, whilst their diameter, on the other hand, appears of increased size. Numerous observations and experiments made by Fodéra, Edwards, Weber, and others, have clearly demonstrated that the volume of a muscle does not appreciably change during contraction.

From recent microscopic observations it would appear that the muscular fibre is composed of a very great number of cells or globules, arranged in longitudinal piles, which, by their union, constitute the muscular fasciculi: it would accordingly appear that a muscle is susceptible of a species of cleaving, both longitudinally and transversely. This structure presents also a great analogy to that of the electric organ of electric fishes, and we have already had occasion to observe that the same laws preside in the main over the discharge of the latter, and over muscular contraction. During the contraction of a muscle, the globules, or, more correctly speaking, the transverse strise of the muscular fibres approach closer to one another, the intervals between them diminish, and the bulk of the fibres increases; whence it results that the volume of the muscle undergoes no appreciable change. According to Bowman, the elementary muscular fibre does not contract simultaneously throughout the whole of its mass, but the contraction is propagated from point to point, of course, with great velocity, yet, notwithstanding, at appreciable intervals of time; a fibre in contraction would, accordingly, constantly present some points in a state of rest, and others in a state of mutual motion towards one another.

Schwann has made some important researches concerning the variations of the muscular force in the divers stages of the contraction of a muscle. We will here simply give the principal result arrived at by this philosopher. The force displayed by a muscle during contraction is invariably proportional to its respective length in the divers instants of the contraction: accordingly this force, very considerable at the commencement of the contraction, diminishes in proportion to the shortening of the muscle, and becomes finally *null* when the contraction is at its maximum. A muscle in contraction may consequently be compared to an elastic thread drawn out by a weight, and which, upon the removal of the latter, resumes its original length with a force invariably proportional to the weight which it had to support, and to the elastic elongation which it had suffered. This result shows the fallacy of the notion which would ascribe muscular contraction to the reciprocal attraction of the globules or elementary particles composing the muscular fibre. Were this the case, the force displayed by the muscle ought to augment during its contraction. The result arrived at by Schwann, on the contrary, might be explained upon the assumption that the contraction is produced by the instantaneous cessation of a repulsion supposed to exist between the discs, and excited the instant immediately preceding its cessation.

The author offers the following hypothesis upon this subject, which he considers based upon well-founded analogies and supported by numerous facts:—The contraction of a muscle

consists in a repulsion between the elementary particles of the muscular fibre immediately succeeded by the return of the fibre to its original state, which return is effected by its inherent elasticity. Accordingly, the nervous action would thus cause the repulsion between the elementary particles of the muscular fibre, which would then, by the dispersion or instantaneous loss of the nervous force, be succeeded by contraction. Imagine to yourself a chaplet formed of globules or discs, kept fixed by springs interposed between them: an electric charge communicated to this system produces, in the first place, repulsion between the globules or discs (supposing these alone susceptible of being electrified); this repulsion will go on increasing in proportion as the electric charge proceeds to the two extremities of the chaplet; the moment the electricity is dissipated, the globules will resume their natural position, after having first passed through an intermediate state of closer proximity to one another resulting from the action of the springs interposed between them.

After these brief generalities on the mechanism of muscular contraction, we have to say a few words on the locomotion of animals.

The locomotive organs of animals may be looked upon as a system of levers of various kinds, of which the length, resistance, and weight, are suitably combined, and to which muscular fasciculi are applied in different ways. The air, the water, the earth, are the mediums in which the movements of animals are executed, and which supply the necessary points of support, or fulcra, for these movements. The theories on the composition of forces, centre of gravity, levers, and resistance of mediums, apply, accordingly, equally to animal machines as to any machine employed in arts or trades.

The brothers Weber have demonstrated by numerous experiments that the inferior extremities of man, when put in motion, oscillate round the trunk, in the manner of a pendulum, by the action of gravity. The experiments were made both upon living individuals and corpses; the duration of the oscillations proved invariably proportional to the square root of the length of the oscillating limb. These movements are thus accomplished independently of the will, which explains the perfect regularity with which steps succeed one another, in children as well as in adults, in idiots as in individuals of great intellectual powers and determined will. The action of the muscles in the execution of these movements is accordingly null, or, at all events, exceedingly limited; the leg raised and left to itself accomplishes the step by the simple action of gravity. The head of the femur has to bear only a very slight friction in turning in the cotyloid cavity, where it is retained by atmospheric pressure, which thus assists in the performance of these movements. The limb does not press with its whole weight against the walls of the coxo-femoral articulation; the head of the femur remains fixed to this cavity by the pressure of the atmosphere, which neutralizes the effect of the action of gravity upon the limb. This action of the atmospheric pressure was likewise revealed by the researches of the brothers Weber. These distinguished philosophers suspended a corpse from a beam, and severed subsequently the muscles which unite the thigh to the trunk: the position of the limb remained unchanged; the cotyloid cavity was then perforated, whereupon the limb immediately fell to the ground; being replaced in the cavity, it was found that it might be made to fall or to retain its place in the cavity by simply opening or closing the aperture which had been made in the latter.

The passive organs of locomotion present, like all other parts of the human machine, a constant application of mechanical principles for the attainment of a very complicated result. If an engineer were told to construct a movable column, composed of a certain number of cylindrical pieces, of unequal length, joined together by their respective extremities; the column to be capable of supporting a considerable weight, and to

resist lateral shocks; the extremities of the levers pieces of the column to terminate in a manner to permit the ready application of the forces which are to put them in motion; the column, finally, to be susceptible of executing a great number of partial movements without its simplicity and elegance being impaired: he would surely declare the task to be, if not absolutely impossible, yet exceedingly difficult.

The bones are composed of a mixture of gelatine and phosphate and carbonate of lime, in different proportions. Changes in these proportions are attended with changes in the degree of tenacity and elasticity of the bones.

The weight and resistance of the bones are also influenced and modified by the respective dimensions and structure of these organs. All the bones of the human frame are constructed in a manner to offer the requisite resistance without excessive increase of weight.

Our knowledge of the muscular power has not much advanced since Borelli's time, about a century ago. The disposition of the muscles is arranged and combined in a manner to obtain the greatest possible celerity and extent of motion, without impairing the simplicity, harmony, and elegance of the divers parts of the human frame. To attain this result, we find the following conditions united in all possible cases:—

1. The muscular fibres are inserted obliquely on the tendon.
2. The direction of the tendon is oblique to the axis on which it is supported and intended to act.
3. The points of insertion of the tendon are near the articulations of the bones, which serve as points of support.

The following are the principles established by Borelli (and generally admitted up to the present day) to calculate the respective force of the divers muscles of an animal:—

1. Two muscles, composed of an equal number of fibrils, and consequently of equal thickness, raise a given weight to heights proportional to their respective length, or, in other terms, they raise to a given height, weights proportional to their respective length.

2. Two muscles of equal length raise to a given height weights proportional to their respective thickness.

We may express these two propositions in more general terms as follows:—The mechanical labour of which a muscle is susceptible varies in the combined ratio of its bulk and length. Of course, in this calculation we are compelled to omit an important element, which is not susceptible of measurement *a priori*, viz., the intensity of the nervous force, which varies under the influence and dominion of the will.

It is easy to understand how the extent of the movement of a bone depends upon the degree of obliquity with which the muscular fibrils are inserted on the tendon, and how this extent increases with the degree of the obliquity.

The obliquity of insertion of the muscular fibrils causes a loss of muscular force, varying with its degree. Such is the general disposition and arrangement of all the motory organs of animals; the reason of this arrangement will be readily understood when we consider that the body of man and animals would present a monstrous shape, were the muscles made to act normally upon the bones.

To diminish the loss of muscular force consequent upon the obliquity of the insertion of the muscles on the bones, the extremities of the latter are made to terminate in spherical knobs and processes over which the tendons glide and attach themselves lower down on the bone.

We have finally to remark that on the relative disposition of the points of support and of those of application of the resistance and of the power in the levers of the animal economy depend the well-known relations between the space traversed by the power, the resistance, and the absolute forces representing them. In general, the levers of the human body are of the third class, so that the lever arm of the resistance exceeds that of the power. The forearm affords

an instance of a lever of the third class, having its point of support in the articulation of the elbow; for resistance the weight of the arm, which is supposed to be applied at the middle of the forearm, and for power the flexor muscles attached to the extremity of the bones of the forearm. To find the numbers expressing the relations of the movements of the power and of the resistance as supplied by theory, it suffices to compare between them the relative distances of the points of application of the power and of the resistance from the point of support. The extremity of the forearm traverses a much greater arc than that described by the flexor muscles; the extremity of the forearm accomplishes its motion with a velocity of 974 millimètres per second, whilst the flexor muscles accomplish theirs with a velocity of only 810 millimètres per second.

In cases where it is necessary to counterbalance a greater force by means of a less considerable force, a lever of the second class is employed; the instance of an individual standing on one leg and supporting on that leg the whole weight of the body, may serve to illustrate this.

Borelli has endeavoured to evaluate the respective force of a great number of muscles. From the numbers resulting from his experiments, he deduced the respective amount of force sacrificed in the majority of muscular movements for the purpose of acquiring velocity. It will suffice here to give one of the cases studied by Borelli. The weight of the forearm of an adult is about two kilogrammes, which may be considered applied at its middle, or, what comes to the same point, may be looked upon as one kilogramme applied at double the distance from the point of support, which simply means placed in the hand. Now, we know that a man is capable of bearing a weight of about thirteen kilogrammes with extended arm; the total resistance to be overcome amounts consequently to fourteen kilogrammes. On the other hand, the lever arm of the muscular power is in length about the twentieth part of the length of the forearm.

Then,

$$14 \times 20 = 280;$$

which means that to carry a weight of fourteen kilogrammes with one hand requires an effort, on the part of the flexor muscles, measured by 280 kilogrammes.

DUMAS ON ORGANIC CHEMISTRY.

No. XXIX.

(Continued from page 528.)

THE BONES.

The bones are resistant organs, destined to sustain and protect the soft parts of the organism. They are essentially composed of two elements: of an inorganic, earthy part, which gives them the solidity which their functions require; and of an organic tissue, formed of a cartilaginous substance, and of the vessels and nerves which we meet with in all organs endowed with vitality. Exteriorly, they are covered by a very vascular membrane, which is named the *periosteum*; sometimes, and especially in long bones, their central part is hollowed into a canal, which contains the marrow. The external surface of the bone is ordinarily very compact; its tissue is more dense than in the interior, where we find, especially in flat bones, osseous cells formed by thin layers or prolongations, constituting a structure which is named the *diploë*.

M. Gahn, the Swedish chemist, was the first to point out the fact, that the inorganic part of the bone is principally formed of phosphate of lime; it, moreover, contains some carbonate of lime, a little fluoride of calcium, magnesia probably in the state of phosphate, and some traces of oxides of iron and manganese. Nothing is more easy than to isolate this inorganic part of the bone. We have merely to calcinate the bone strongly, in contact with the air, to destroy

entirely all the organic substances, and thus produce a perfectly white earthy residue, which ordinarily preserves the original form of the bone. If we perform this calcination in closed the organic matters, in place of burning, merely carbonized, and we obtain a residue which serves for the preparation of ivory-black.

It is easy to extract from the earthy matter of the bone all the inorganic materials of which it is composed. We are already acquainted with the mode by which we are enabled to extract its phosphorus. The composition of the bone of lime, contained in the bone, may be represented, according to Berzelius, by the formula: $3P_2O_5 \cdot 8CaO$. But, as M. Mitscherlich has remarked, it may readily happen that a salt will contain a little more lime, when its composition will be represented by the more simple formula: $P_2O_5 \cdot 3CaO$, and which, moreover, will be found more in harmony with the general constitution of the phosphates. To demonstrate in the calcined bones the presence of magnesia, we should dissolve them in nitric acid; to this we add ammonia, until the liquor begins to grow cloudy, and then precipitate the phosphoric acid by means of acetate of lead; having filtered the liquid, we separate the lime, by the aid of oxalate of ammonia, and, after renewed filtration, we thus obtain a solution which, when evaporated and subjected to calcination, furnishes a residue of magnesia, mixed with some traces of oxides of iron and manganese.

As to the fluoride of calcium, we may assure ourselves of its presence by decomposing a certain quantity of calcined and pulverized bones, by sulphuric acid, in a platinum capsule. The vapours which escape, on the application of heat, are capable of corroding glass.

We find in bones, when calcined to a state of whiteness, a small quantity of sulphate of lime, which did not exist there before calcination. The sulphuric acid is, in this case, no doubt formed by the oxidation of the sulphur, which is contained in the animal matters with which the bone is impregnated.

We may completely extract the earthy substances of the bone by digesting it in cold dilute hydrochloric acid; the inorganic salts are dissolved, and the cartilaginous matter and the vessels remain under the form of a soft, flexible, and transparent mass, which, by ebullition with water, is almost entirely resolved into gelatine. Strong hydrochloric acid, even when cold, removes along with the inorganic salts a portion of the animal matter. If we wish, therefore, to determine with exactitude the relation of the inorganic elements as compared with that of the organic principles of the bone, we must employ a very dilute acid; or, better still, we may have recourse to pure and simple calcination. During the action of hydrochloric acid on fresh bone, we remark a disengagement of carbonic acid—an evident proof that this acid is not the product of calcination alone.

The first analyses which were made on bones, in the normal state, are due to M. Berzelius. The following are the results he obtained:—

	Bone of water	Bone of
Cartilage completely soluble in water	32.17	33.30
Vascular tissue	1.13	
Basic phosphate of lime, with a little fluoride of calcium ..	53.04	57.35
Carbonate of lime	11.30	3.85
Phosphate of magnesia	1.16	2.05
Soda with a very little chloride of sodium	1.20	3.45
	100.00	100.00

Before subjecting these to analysis, the bones had been carefully freed of their pericosteum, fatty matters, &c.

M. Marchand found in the femur of a man, thirty years of age, the following substances:—

Cartilage insoluble in hydrochloric acid ..	27.28
Cartilage soluble in hydrochloric acid ..	8.08

Vascular tissue	1.01
Basic phosphate of lime	53.26
Fluoride of calcium	1.00
Carbonate of lime	10.21
Phosphate of magnesia	1.05
Soda	0.92
Chloride of sodium	0.25
Oxide of iron, oxide of manganese, and loss ..	1.05
	100.00

Annexed are some analyses of human bones made by M. Valentin:—

	I. Cortical substance of the tibia of a man.	II. Medullary substance of the same bone.	III. External condyle of the femur of a young girl.	IV. Head of the tibia.
Cartilages, vessels, &c. ..	38.02	41.16	41.18	48.36
Inorganic materials ..	61.98	58.84	44.82	51.44
Basic phosphate of lime ..	52.93	49.03	37.01	41.77
Carbonate of lime	7.66	7.76	5.04	7.11
Phosphate of magnesia ..	0.25	1.54	0.87	0.88
Chloride of sodium	0.91	0.44	0.65	1.67
Carbonate of soda	0.28	0.07	1.43	

By comparing these with the foregoing analyses, we find them distinguished by a less considerable proportion of inorganic materials—a result which is probably owing to their less perfect desiccation. We may, however, perceive that the relation between the organic elements and the inorganic parts of the bone is far from being constant, and that it varies according to the nature of the bone and the age of the individual. Dr. Rees has made some careful experiments, for the purpose of elucidating this part of the subject, with the bones of an adult man, and with those of a stillborn child at the full term

	Bones of an adult man.		Bones of a stillborn child.	
	Inorganic materials.	Organic materials.	Inorganic materials.	Organic materials.
Tibia	60.01	39.99	56.52	43.48
Femur	62.49	37.51	57.51	42.49
Humerus	63.02	36.98	58.08	41.92
Fibula	60.02	39.98	56.00	44.00
Ulna	60.50	39.50	57.50	42.50
Radius	60.51	39.49	56.50	43.50
Temporal bone ..	63.50	36.50	55.90	44.10
Vertebra	57.42	42.58	—	—
Rib	57.49	42.51	53.75	46.25
Clavicle	57.52	42.48	56.75	43.25
Ilium	58.79	41.21	58.50	41.50
Scapula	54.51	45.49	56.60	43.40
Sternum	56.00	44.00	—	—
Metatarsus	66.53	33.47	—	—

These analyses, like those of M. Valentin, present an excess of organic matters which we must probably attribute to the causes already pointed out. Such as they are, however, they give ground for some interesting remarks. They show, for instance, that the bones of the cranium are richer than most others in earthy salts. The long bones, which, by the nature of their functions, also require great solidity, very nearly approximate the cranial bones in their proportion of phosphates. As to the ribs, the vertebrae, the clavicle, the scapula, and the sternum, they present a composition analogous to that of the bones of infants, being comparatively soft and vascular, and of which some become hard only at an advanced stage of life.

The quantity of earthy substances in the bone augments in proportion as the individual advances in age; such, at least, would appear to be the case from the following analyses, performed by M. Schreger:—

	Bones of the infant.	Of the adult.	Of the old man.
Organic matters	47.20	30.18	12.2
Earthy substances	48.48	64.84	84.1
	95.68	95.02	96.3

We possess but very incomplete data as to the composition of the bones in animals. M. Barros has made some comparative analyses on this subject, so as to determine the relative proportions of phosphate and of carbonate of lime. The following are the results which he obtained:—

	Phosphate of lime.	Carbonate of lime.
Bones of the lion	95.0	3.8
„ sheep	80.0	19.3
„ fowl	88.9	10.4
„ frog	95.2	2.4
„ fish	91.9	5.3

From these imperfect analyses it would appear, that the bones of the *herbivora* and of the *gravidora* are richer in carbonates than are those of other animals.

M. Chevreul has given us an analysis of the cranial bones of the codfish. He found in them:—

Animal matter and moisture ..	43.94
Phosphate of lime	47.96
Carbonate of lime	5.50
Phosphate of magnesia	2.20
Salts of soda	0.80

M. Dumenil found in the bones of the pike:—

Animal matter	37.36
Phosphate of lime	55.26
Carbonate of lime	6.15
Soda, chlorides, phosphates, and loss ..	1.23

The bones of these fish present, as we see, a composition analogous to that of the bones of the mammifera. But there exists a class of fish of which the osseous system offers a totally different composition: these are the cartilaginous fish. M. Chevreul, who analyzed the bones of an individual of the species called *squalus peregrinus*, found in them but a very small quantity of inorganic matters. The cartilaginous substance forming them is transparent, of a bluish colour, flexible, and easily divisible into very thin layers. It gradually swells up when placed in hot water, at the same time preserving a perfect transparency; it requires for its solution 1000 times its weight of boiling water. This solution is not precipitated by tannin, nor does it become converted into a jelly by evaporation. Alcohol renders it of a firmer consistence, and partly destroys its transparency. Hydrochloric acid dissolves it, and this solution is precipitated by tannin. We thus see that this matter differs in its properties from albumen and gelatine, and that it somewhat resembles mucus.

The analyses of M. Marchand would seem to indicate, in the bones of the cartilaginous fish, a rather large proportion of earthy salts. The following are the results obtained by this chemist:—

	Vertebra of a <i>squalus cornubicus</i> .
Organic matter	57.07
Phosphate of lime	32.46
Sulphate of lime	1.87
Carbonate of lime	2.57
Phosphate of magnesia	1.03
Sulphate of soda	0.80
Soda and chloride of sodium	3.00
Fluoride of calcium, silica, alumina, oxide of iron, and loss	1.20

	Bones of the head of a <i>squalus peregrinus</i> .
Organic matter	78.46
Phosphate of lime	14.20
Carbonate of lime	2.61
Sulphate of lime	0.83
Sulphate of soda	0.70
Chloride of sodium	2.46
Fluoride of calcium, phosphate of magnesia, and loss	0.74

It is probable that the sulphates, which M. Marchand has pointed out in these bones, are formed solely during incineration: a remark which he has himself made elsewhere.

When the bones are abandoned for a length of time to the action of the air, the organic tissues gradually disappear, and there eventually remain but the earthy substances. This decomposition is effected in a very gradual manner; and, should the bone be buried deep in the

earth, we may readily comprehend that it may last for several ages. We often meet with fossil bones which still contain a large proportion of organic matters—a fact which is proved by the annexed analyses. Stokes and Apjohn found, in a rib of the *ceruus megacerus* of Ireland:—

Animal matter	42.87
Carbonate of lime	9.14
Phosphate of lime with fluoride of calcium	43.45
Silica	1.14
Oxide of iron	1.02
Water and loss	2.38

M. Marchand analyzed two fossil bones of the bear, the one of which had been found on the surface of the soil, whilst the other had been dug from a considerable depth. The following are the results he obtained:—

	I.	II.
Animal matter	4.20	16.24
Phosphate of lime	62.11	56.01
Carbonate of lime	13.24	13.12
Sulphate of lime	12.25	7.14
Fluoride of calcium	2.12	1.96
Phosphate of magnesia	0.50	0.30
Silica	2.12	2.15
Oxides of iron and of manganese	2.12	2.00
Soils and loss	1.34	1.08

100.00 100.00

We thus see that the bone found near the surface of the soil, and which, consequently, had been subjected to the more direct action of oxygen, had undergone a greater degree of decomposition than the other. But the influence of position on the composition of fossil bones is not confined to the mere hind-ring or favouring of the action of the air. We can readily understand how various foreign mineral matters may, by a slow but continuous process of infiltration, penetrate gradually into the very substance of the bone. It is in this way that we are enabled to explain the large proportion of sulphate and carbonate of lime, as well as of silica and oxide of iron, which the foregoing analyses indicate in fossil bones. M. Liebig has found in some cranial bones, which have been exposed during the excavations that have taken place at Pompeii, a greater proportion of fluoride of calcium than in ordinary bones. The excess of this salt must, in like manner, be attributed to the cause of which we have just been speaking, unless we admit, and this indeed seems a very unlikely supposition, that the crania of the ancient Romans were richer in fluoride of calcium than are our own.

The influence of infiltration upon the composition of fossil bones is shown in a very clear manner by the analysis made by Vauquelin upon the fossil bones of Montmartre, which contain a large quantity of sulphate of lime, evidently drawn from the soil which holds them; he there found—

Carbonate of lime	7
Sulphate of lime	28
Phosphate of lime	65
Water and traces of animal matter	10

Composition of Diseased Bones.—When we place in contact the fragments of a broken bone, the two ends secrete a cartilaginous substance, in which is gradually deposited phosphate of lime, for the purpose of soldering the fracture. It is to this mass that the name of *callus* has been given. M. Lassaigne has respectively analyzed this callus and the bone upon which it was formed. The following are the results which he obtained:—

	Callus.	Bone.
	Exterior.	Interior.
Organic matter	48.5	50.0
Phosphate of lime	32.5	33.0
Carbonate of lime	6.2	6.7
Soluble salts	12.8	11.3

The callus was thus found to be less rich in earthy matter than the bone itself.

According to MM. Lassaigne and Valentin, exostoses present an analogous composition to the callus, and, like it, contain less phosphate of lime than does the sound bone. Annexed are some comparative analyses made by M. Lassaigne:—

	Fresh bone.	Condensed bone.	Exostoses.
Organic matter	41.8	43.0	46
Phosphate of lime	41.6	36.3	30
Carbonate of lime	8.2	6.5	14
Soluble salts	8.4	14.2	10

Rachitism is frequently manifested by a peculiar alteration of the bones, known under the name of *ostomalacia*. In this disease, these organs lose a part of their phosphate of lime, thus becoming soft, and sinking under the weight of the body. Bostock and Proesch have analyzed the bones in this altered condition, when they found:—

	Bostock. Vertebra.	Proesch. Vertebra.	Rib.
Cartilage	79.75	74.64	49.77
Phosphate of lime	13.60	13.25	33.60
Ditto of magnesia	0.82	—	—
Carbonate of lime	1.13	5.95	4.60
Sulphate of lime and phosphate of soda (?)	4.70	0.90	0.40
Fatty matter	—	5.26	11.63

ORIGINAL CONTRIBUTIONS.

ON THE PHYSIOLOGICAL AND PATHOLOGICAL CAUSES OF SUDDEN DEATH IN CONNECTION WITH THE NERVOUS SYSTEM.

By M. W. HILLES, Esq.

(Concluded from p. 493.)

The fatality attendant upon diseases and injuries of the nervous system, then, depends upon the peculiar part affected, and the special function implicated; the suddenness or rapidity of the fatal termination being in proportion to the connection which this function maintains in, and the influence which it exercises upon, the animal economy.

The simplest office of the nervous system is that of endowing the muscles with the degree of nervous energy which is necessary to *motion*: thus, for example, it confers on the muscles of the extremities their powers of contraction, as also upon the muscles of the eye, &c.

If that portion of the nervous system which endows these muscles with mobility be destroyed, either by disease or accident, the result is loss of motion; but as this is not, in most instances, essential to life, death does not supervene: the extremities may be paralyzed, or the eye lose the power of motion, without serious injury to the vitality of the individual.

In some instances, the simple loss of motion is followed by rapidly fatal consequences, as, for example, in those cases of injury to the spine and spinal marrow, in which the nervous structure is destroyed, above the origins of the respiratory nerves. Here, the mechanical act of respiration cannot be performed, and, therefore, this action—one of those on which life depends—being suspended, death immediately results.

The rapidly fatal effect of loss of the nervous muscular energy, on the organs essential to the organic life, is still more evident where the sympathetic nerves are affected, as these preside over the heart and circulation, and create a material influence in all the vital functions.

The diseases of the sympathetic have been so little studied, and are, as yet, so imperfectly known to us, that we can draw but few conclusions from the morbid condition of this system, but accidents afford us numerous instances, which all furnish us with sufficient evidence of the correctness of these remarks.

I allude now to blows or injuries upon the epigastric region, immediately over the solar plexus of nerves. Many cases of slight blows in this situation are recorded in which death took place instantaneously; one of the most remarkable occurred a few years since in the neighbourhood of the London Docks. A porter was endeavouring, but without avail, to raise some heavy substance; one of his comrades approached and in a jocular manner said, "Stand aside and give way to abler men," at the same

time striking him gently over the epigastric region; the poor man instantly fell dead. On a *post-mortem* examination no organic lesion could be detected.

How are we to explain this suddenly fatal termination? I would say, by referring death to the concussion of the solar plexus. We must regard the solar plexus as the centre of the sympathetic nervous system, as the brain is the centre of the nervous system of animal life, and that, in these cases of blows or injuries, it suffers a degree of concussion similar to that endured occasionally by the brain; and that this concussion so disturbs, impairs, or destroys the nervous energy of the organs of organic life, supplied by the sympathetic system, as to cause the suspension of their functions, and, as a necessary consequence, the destruction of the vital functions and life of the individual.

Blows on the epigastric region frequently prove fatal, by causing a rupture of one or more of the viscera; these, however, do not belong to our present subject, as they are seldom productive of sudden death, some days usually elapsing between the receipt of the injury and the fatal termination.

Some few of these injuries are immediately fatal, from their great violence, or from the rupture of the stomach or liver, or some of the large blood-vessels in the abdomen; the immediate cause of death in such instances is sufficiently obvious.

Lesions, then, may occur in any portion of the nervous system without compromising the life of the individual, so long as they do not extend to those portions which control the animal and, still more especially, the organic life.

Sense and sensibility may be wholly destroyed, and yet life may be preserved for a considerable length of time. *Motion*, that is, voluntary motion, may be extinguished without a fatal result; the organs which sustain organic life, namely, the heart, lungs, and digestive viscera, maintaining their action, life is sustained.

In this condition man appears to be reduced to a state, as it were, of vegetative existence: all the qualities which distinguish him as a superior being have been effaced, and he lives only as the meanest vegetable, imbibing nutrition from the various elements introduced into contact with his digestive viscera, and elaborating life, such as it is, from these and the other viscera of organic existence.

It is difficult to say how long a human being may continue in this condition. Sir A. Cooper relates the case of a sailor who remained for upwards of twelve months in a state of unconsciousness, the result of an injury to the cranium; in which condition he continued to take nourishment, and perform all the functions of organic existence, although all other functions seemed to be perfectly suspended. In this case there was no lesion of any portion of the nervous system; the symptoms were wholly induced by a portion of bone which, being depressed, caused a compression of the brain and a suspension of all its functions.

It is evident that the sympathetic system was unaffected in this case.

An operation having been performed, the patient recovered all his faculties in a few days, and was restored to perfect health.

Injuries to, or lesions of, the nervous system of animal life are more fatal than those which affect the intellectual existence. This is evident from the fact, so frequently observed by all writers, of the greater fatality attendant upon injuries of the cerebellum than of the cerebrum.

But in what manner is the animal life, or are the animal instincts, of the individual more closely connected with the organic life, that it should suffer more immediately, when they are injured or destroyed, than in cases where the intellectual functions are impaired?

Anatomy does not disclose a more intimate connection between the animal and organic than between the intellectual and organic functions; the sympathetic system is connected with the cerebrum by means of the sixth nerve, but is not

directly connected with the cerebellum by any more special nervous filaments. The indirect connection, however, is greater by means of the anastomosis which is established between the sympathetic and the branches of the eighth pair of nerves, and, in particular, the pneumo-gastric, the mode of origin of which associates it with the functions of the cerebellum.

The phenomena observed in connection with the diseases of idiosyncrasy and insanity support these views, and establish the little relation which lives.

principle depends; the unfortunate individual, in such instances, possesses but the animal and organic functions, and lives in a condition but little, if at all, removed from the brute creation.

Shall we pause here to inquire as to the state or condition of the soul in such persons? How can they who support the opinion that the mind and soul are one, reconcile the existence of the latter, in cases where the former is evidently destroyed, or, perhaps, has never existed?

Man is evidently composed of three great functions, the organic or vegetative, the animal, and the intellectual. The first sustains the living principle, and maintains the body in its healthy condition, precisely as the vegetable kingdom is sustained by its organs; the second furnishes him with those instincts and passions peculiar to the animal, and which we must suppose to be wanting in the vegetable; the third raises him in the scale of creation, and places him, by its superiority, above all other earthly beings.

Of these three, the organic is the most, the intellectual, the least essential to life.

PART II.

On Cases of Sudden Death produced by Impressions made on the Nervous System, or some part thereof, without Lesion or Morbid Alteration.

Under this head we shall consider some of those extraordinary cases of sudden death which occur occasionally, and present no trace after death of the immediate cause of the loss of life.

These cases occur more frequently than is generally imagined, and may be found recorded in most medical writings: the following is an instance which fell under my own observation:—

One of the nurses in the Westminster Hospital, about forty years of age, in the enjoyment of apparently perfect health, and whilst engaged in the discharge of her duties, dropped suddenly dead.

A careful examination of the body was made, but all the organs were perfectly healthy, and no trace of organic lesion could be found to explain the immediate cause of death.

It is extremely difficult in such cases to account for the cessation of the vital actions, as we do not see any reason why any one of the great vital functions should spontaneously cease its action. We must refer death to some derangement of the nervous system, the intimate nature of which is beyond our investigation: it may be that the secretion of the nervous influence is, from some peculiar cause, suspended, or, if secreted, is interrupted in its passage through the cerebral mass, or along the nerves; but these are conjectures which afford but little satisfaction to the inquirer.

It is not likely that death is caused by any suspension of the respiratory or circulatory functions, as these are mechanical actions which must proceed so long as the muscular agents engaged continue in healthy state. A serious departure, also, from the healthy state in the structure of the blood-vessels or lungs is easily observed and recognised: it is otherwise in the nervous system, in which the actions are of too complex a character to be fully understood by us at present, either in the healthy or morbid state.

Of a somewhat similar nature are those cases of sudden death which occur from sudden and violent mental impressions, such as fear, anger,

&c.; here there can be little question that the nervous system is the structure primarily affected, the injury to which leads to a total suspension of the vital actions.

We may include under this head, also, those cases of sudden death which occasionally occur from discharges of the electric fluid during thunder-storms. In the majority of these cases the fatal impression is exerted on the nervous system, this being especially acted upon by electricity. Some cases present traces of combustion having occurred from the electric fluid; but in such this can have had little effect in producing death, as the shock to the nervous system is sufficient, *per se*, to destroy life. The combustion, in all probability, occurs after life is extinguished.

As the nervous system presides over all the actions of the animal economy, and regulates the various offices of the intellectual, animal, and organic lives of the individual, we need not be surprised that injurious impressions made upon any important portion of it should lead to serious consequences, or that one or other of these should suffer.

It is not necessary that organic lesion should exist, or be found, in these cases after death; there is a functional as well as an organic derangement of the nervous system which interferes with, or may destroy altogether, the healthy condition, and lead to a fatal termination.

How many instances of this present themselves in practice! Epilepsy, hysteria, and the class of affections usually termed nervous, are generally functional derangements of some portion of the nervous system, presenting symptoms, we may be assured, in accordance with the peculiar part affected, although our present knowledge of the intimate structure and functions of the nervous system is not sufficient to ascertain with precision the part originally disordered.

How much remains to be done! What vast discoveries are yet open to the diligent inquirer!

Who shall discover the precise nature of the nervous fluid?—who reveal its mode of action in the animal economy? Who shall unfold the mystery that still attaches to the optic thalami, the corpora striata, the corpora albicantia, and the various other bodies, large and small, of every size and shape, of which the brain is composed?

We may rest assured that each one of these bodies has its office or use, and that each contributes to the production of some one of those manifestations of nervous power which equally delight and surprise us.

Each of the feelings, passions, or propensities of humankind has its resting-place in the brain: this body gives to the man the passions of the beast, that raises his fellow to the dignity of the philosopher or the statesman.

We are but creatures composed of an assemblage of atoms, exposed to the impulse of passion, the violence of feeling, the anguish of disease. Left to these, we were truly miserable; but, endowed with reason, man stands forth as a being that should be superior to the animal propensities which so often divert him from the true, the legitimate object of his creation.

What strength and what weakness, what beauty and what deformity, does he not combine within him! How noble a creature when in pursuit of all that tends to the perfection of nature and the happiness of his species!—how contemptible when enlisted in the cause of degradation and destruction!

At one moment in the enjoyment, apparently, of the most perfect health, he sinks the next to the earth, a mass of pestilence and disease.

Man being indebted for his existence to the three great vital functions—namely, respiration, circulation, and that of the nervous system, all and each of which are necessarily in constant action to sustain life—it follows that, any one of these being arrested, death follows rapidly, if not immediately; hence, in all cases of sudden death we may feel confident that one or other of these functions has been destroyed, and that all

agents which are rapidly destructive of life operate upon one of these.

In the more gradual decay of the human powers, which we observe to take place in old age, death is produced equally by the suspension of the vital functions. The respiration is embarrassed, the circulation is languid and imperfect, the nervous energy impaired. By degrees, these become more imperfect, until man is reduced to a state of vegetative existence, in which the higher functions of the nervous system, viz., intellectuality and animal instinct, are nearly extinguished, and those offices only remain which minister to the support of the physical wants of the animal; these gradually cease to exist, and man returns to the elements from whence he derived his corporeal existence.

This gradual extinction of the human being is strikingly analogous to his original growth—at first, enjoying but a vegetative existence in the mother's womb, he progresses until the higher qualities of the species become superadded, and man becomes the perfect animal, the lord of the creation.

What an interest attaches, painful though it be, to even the decay of our frames, the progressive destruction of our existence! Man, by this gradual loss of the intellectual powers and animal instincts, feels but little interest in secondary objects, at one time so dear to him, and perhaps less regret that he is so soon to part from them; he is thus wearied, as it were, from the things of this world, and enters without reluctance, if not with joy, upon the life to come.

Death, if not premature, should not therefore be a cause of grief: we might as reasonably lament the melting of the iceberg, or the dropping of the ripened fruit, or the fall of the autumn leaf. They are all equally the result of natural laws, to which man must yield, even as the insensate mineral.

It is difficult, however, so to chasten the mind as not to feel regret at the decay of one, perhaps dear to us, and particularly so when that discloses itself in the production of a sudden death. In such cases many circumstances combine to impress the human mind with painful sensations.

This concludes the series of papers on the "Physiological and Pathological Phenomena of Sudden Death." I propose, at some future period, to enter upon the Phenomena of Sudden Death produced by Poisonous Substances.

MEDICAL APPOINTMENTS.—W. Dashwood Kingdon, M.D., has been elected Resident Medical Superintendent to the St. Thomas's Hospital for Lunatics, near Exeter, in the room of Luke Ponsford, Esq., resigned.

APOTHECARIES' HALL.—Gentlemen admitted members September 2: William Charles Homfray, and John Lucas Worship.

IMPROVEMENTS IN GUN-COTTON.—Mr. Costhup recently forwarded to the Chemical Society two specimens of gun-cotton, with a view to illustrate the greatly increased explosive effects that are to be derived from a subsequent immersion of the gun-cotton, when properly prepared in the ordinary way, in a saturated solution of chlorate of potash. "Having experimented with solutions of nitrate of ammonia, nitrate of potash, nitrate of soda, bichromate of potash, &c., for the purpose of increasing the explosive properties of this interesting substance, I can affirm that none of the results will bear the slightest comparison with those obtained from the solution of chlorate of potash, either in rapidity of ignition or in intensity of flame. The process adopted for preparing the enclosed specimens was as follows—viz.: into a mixture of equal measures of strong nitrous acid, and of oil of vitriol, spec. grav. 1.848, the cotton was immersed and stirred with a glass rod during about three minutes; it was then well washed in many waters and dried; a portion of it was then soaked for a few minutes in a saturated solution of chlorate of potash, well squeezed and dried."

THE PHYSIOGNOMY OF DISEASES OR SEMIOTICS IN THEIR ASSIMILATIVE CHARACTERS.

By GEORGE CORFE (Author of "A Popular Treatise on the Kidney," &c.), of the Middlesex Hospital.

[Illustrated by Portraits of Cases.]

(Continued from p. 561.)

Thus that wonderfully penetrating organ, the eye, is the grand instrument employed in primarily searching out the patient's real state, as he presents himself to the medical man. Having caught his glance, if he is able to raise the lid, you have an amazing volume of mute expression conveyed to your mind for research.

It is related of a Moslem prince that he did but plunge his head into a vessel full of water, remain a few seconds, and come out again, when the adventures of seven years filled his mind. What are the ideas which fill our mind when we deliberately fix our eye upon the eye of another mortal, whether he be in or out of health? Even Lavater has not exhausted the subject. It is, therefore, vain to attempt to enlarge upon it. This only need be said, that every man is influenced by physiognomy, and that, whether he acknowledges it or not, he cannot but be so, for it is in his very nature to be thus wrought upon; and the structure of the human face, compared with that of the highest order of brutes, at once exhibits the human countenance to be endowed with powers of expression which are in vain sought for amongst the lower animal creation.

"The inner extremity of the eyebrow and angle of the mouth are most moveable, and in these we should expect to find the muscles of expression peculiar to man. This superiority of expression in man depends on the action of muscles peculiar to him, and the sole destination of which seems to be limited to this greater aptitude of expression. The systematic provision for that mode of communication, and that natural language which is to be read in the changes of the countenance, are to be found in this peculiarity of muscles. There is no emotion in the mind of man which has not its appropriate signs, and these muscles in the human face can have no other use assigned to them than to serve as the organs of this language. On the other hand, there is in the lower animals no range of expression which is not fairly referable, as a mere accessory, to the voluntary or needful actions of the animal; and this accessory expression does not appear to be, in any degree, commensurate to the variety and extent of the animal passions. These muscles indicate emotions and sympathies of which the lower animals are not susceptible; and, as they are peculiar to the human face, they may be considered as the index of mental energy in opposition to mere animal expression." (a).

"It is related of an eminent physician that on approaching a patient, even whilst asleep, he would express his sentiments respecting the nature of the affection and condition of the patient, the justice of which time and the events have verified. This circumstance proved that there was something in the general aspect and appearance of diseases on which the experienced physician forms a diagnosis, and which it would be of the greatest utility to analyze and describe." (b).

In all serious diseases which involve vital organs there are particular features depicted on the countenance, the meaning of which cannot escape the attention of an observant medical physiognomist. But the grand secret in this most valuable and too much neglected study is to simplify, to abstract, and to separate the main features, with which it is of importance to be acquainted. This is not the work of a day, nor is it to be attained by mental study, but solely by careful, persevering, and attentive observation in the wards of a large hospital, where diversity of

disease and consequent varieties in physiognomy, are constantly presented to the eye of the medical student. It is of the utmost importance that the pupil should accustom himself to learn first to recognise the disease of the patient, before he interrogates him as to his sufferings, ailments, or the history of his illness; and he cannot accomplish this desirable end by any other means than by the study of the physiognomy, attitude, general appearance, gait, and form, &c. &c., of his patient. He should, therefore, strive to seize promptly, and to impress powerfully on his mind, the essential traits of the varied diseases which he is studying, as they are portrayed in the countenance, aspect, and carriage of the patient. Let him first run his eye over the face, and get that by heart, so to speak. Let him then endeavour to pick out, in his mind, the positive features in the face which are characteristic of positive changes in the internal organs. Thus, if a countenance is inanimate, the eye dull, the cheeks of a dusky red, the eyelid drooping, the brow overhanging; the lips dry, herpetic, and of a claret colour; the chest passive, but the abdomen active in respiration, the breathing hurried, and the skin hot and dry, the physiognomist almost instinctively decides in his own mind, before he has addressed himself to the patient, that pneumonia is raging within; whilst, on the other hand, he passes on to a farther bed and views a pale face, an anxious and distressed eye, a puffy blanched lid, *alae nasi* actively engaged in respiration, the angles of the mouth slightly drawn down, the lips separated, the cheeks somewhat bloated and greasy, the jugulars distended, the carotids oscillating, the præcordial region full and more rounded than its opposite, he, moreover, recognises acute rheumatism in the smaller joints, and instantly his mind fastens upon the pericardium as the seat of a mortal disease. His ear further instructs him in both instances, by developing to his mind some of the sounds peculiar to active pneumonia, or to inflammation of the heart and its investing membrane. Now, it may be affirmed that, whenever the principal features of a disease are thus portrayed in the countenance, the accessory traits of the disease will be equally as significant and striking. It would be superfluous almost to add that, when auscultation is brought to bear upon the foregoing and other diseases of the chest, the physician is as certain of the actual morbid changes, and of the varied stages of those changes, that are going on in his patient as if they were laid out before his eye in the dead body; and assuredly he must be better acquainted with the phenomena of these morbid processes than he can be of those changes in organs which he can neither see, nor feel, nor hear.

But to return to the expression of the eye under disease in some vital organ. Who can delineate the variations, the shadows, the languor, the lethargy, the imploring look for help, the impatience, the terror, the anxiety, the havoc which disease is making, and the stamp of which is pictured in the eye, its brow, and its lid? The intimate communications of the fifth pair and seventh, or nerve of expression, with the sympathetic, through the medium of the ciliary, optic, and Meckel's ganglions, would be alone sufficient to expect that this organ of sense should readily exhibit in its altered appearances, the derangement of internal and vital organs. This expressive, though silent organ, may be bright or dull, heavy or clear, half shut or unnaturally opened, sunken or protruded, fixed or oscillating, straight or distorted, staring or twinkling, fiery or lethargic, anxious or distressed; it may be watery or dry, of a pale blue, or its white turned yellow, or its white blood supplanted with red blood. Its vibrations and changes often cannot be numbered, they are so evanescent and so sudden. The pupils may be minutely contracted or widely dilated; insensible to, or intolerant of, light; oscillating or otherwise; unequal in their sizes, and deflected from their clearness. Then we view the brow, that wonderful appendage of expression in a human face; this, too, has its silent language: it may be overhanging, convulsed,

gated, raised, or depressed (a), whilst the lid exhibits its alternations of puffiness or hollowiness, of smoothness or unevenness, of darkness or paleness, of sallow or brown, of white or purple. Lines intersect the region, and the varied tints are perpetually giving new colour, new feature, new expression, by their shadows. Such is the eye, with its brow and lid. Here, then, is the region we enter on. Let the pencil which can best portray take up what the keenest eye can give, and yet is the outline but feeble, so much for mortal power.

Nor is the mouth inferior in expression to the eye. As the greatest portion of the beauty of a face resides in the mouth, so is this department of physiognomy most significant in nearly all those internal diseases which fall upon organs essential to life. "If the angle of the mouth is depressed, it gives an air of despondence and languor to the countenance. When the corrugator supercilii co-operates with it, there is mingled in the expression something of pain. If the frontal muscle joins its operation, an acute turn upwards is given to the inner part of the eyebrow, very different from the effect of the general action of the frontal muscle, and decidedly characteristic of an agonising, debilitating pain, or of discontent, according to the prevailing cast of the rest of the countenance." (b)

"Every passion of the human frame runs throughout the lips to tell its tale. We may call the mouth eloquent in its silence, and speaking, though it be shut. Like the bursting bud, it parts for a smile; it expands for laughter; contracts in rage; curls for disdain; and opens for fright. In its every movement it works with the nostril. Here is union, sympathy, and help. Both assist in producing lineage, and both stamp a joint meaning and cause. In all the depressing influences which act upon the mind, the eyebrow, eyelid, nostril, and angle of the mouth are depressed, whilst these parts of the face are raised in the emotions of joy, laughter, &c. &c. Who cannot read a harassed state of mind in the upward inversion of the eyebrow, with a depression of the angle of the mouth? Here, then, is another region not so vast as that above, but full of interest, grandeur, variety, and use, to him who studies the beauty, the deformities, the virtues or the vices, the health or the diseases, of his fellow-man."

We may now make an attempt to catch some of the points just hinted at, and will enter upon the consideration of the disease called

APPLEXY.

Apoplexy, or in other words, sanguineous effusion into or upon the substance of the brain, is the result of a blow, but more frequently the effects of a ruptured blood-vessel in the cerebral arteries, and occurs usually after forty years of age. Allied to this, there is also ramollissement, or softening, of some portion of the brain; and this ordinarily occurs in the upper or inferior surfaces of the brain, but rarely so in its substance. It is a disease, also, of advanced life. With the former disease there is seldom hemiplegia: if the blood has escaped into the lateral ventricles, crura cerebri, or pons varolii, insensibility is complete, and death is speedy. On the other hand, if the blood has only escaped into one corpus striatum, or thalamus optici, or one of the walls of the lateral ventricles, hemiplegia is then an early evidence of such an effusion; insensibility is not quite so complete as in the former case, and death is more protracted.

(a) In smooth, unruffled countenances, the four muscles peculiar to the human face are poised and counteract each other. In drunkenness, which often produces a temporary paralysis, the eyebrows are sometimes unequally elevated. It is an unusual exertion of the frontal muscle to counteract the heaviness of the eyelids, which produces the elevation of the eyebrows. This web of muscular fibres, which is expanded on the forehead in man, is reflected off from the skull to the ear in lower animals.—Sir C. Bell's "Anatomy of Expression," 4th ed.

(b) Sir C. Bell, *op. cit.*

(a) From Sir Charles Bell's admirable and scientific essays on the Anatomy of Expression.

(b) "On Diagnosis," by Dr. M. Hall, 8vo. 1817.

In ramollissement, however, the paralysis, though present, is not an early indication of this disease; consciousness is not altogether gone, and the sufferer lingers on to a much more protracted stage than in the former two states of cerebral lesion.

The following instances exemplify this complete and partial insensibility in apoplexy.

Susan Cole, forty-five, a short bulky woman, brought in by the police, senseless. She was found, an hour before her admission, on the pavement, in the dark. No account could be obtained of her previous condition. No one saw her fall, or heard her speak. Her state was as follows:—Countenance tranquil, just like a person in a deep sleep; veins of the neck not turgid; mouth open; tongue protruded and swollen; eyes closed, pupils reduced to a small pin's head in size; breathing natural. A brandy bottle was found on her, empty. Pulse 86 and full. We had a suspicion that she had taken opium in some spirituous liquid, and therefore washed out the stomach, with some difficulty, by the stomach-pump, but no traces of any narcotic fluid could be detected. She felt when pinched. There was no paralysis. A drop of croton oil was placed on the tongue, the head was shaved and covered with a blister. She was bled to a small amount, as the vein would yield but little. A turpentine enema was administered; the bladder emptied of a quart of high-coloured urine. Pulse became slower and feebler, and she lingered fifteen hours from the attack.

Autopsy Twenty-four Hours after Death.—Chest conoid; heart enlarged; fluid blood in both its ventricles: left much hypertrophied; capacity natural; a few atheromatous deposits on the aorta, above the sigmoid valves. Stomach healthy, but mucous lining softish. *Head.*—Turgescence of all the cerebral veins; lateral ventricles filled with a sero-sanguineous fluid, and a clot of blood floating in it. On raising the fornix the walls of the third and fourth ventricles were lacerated, laid open, and filled with blood; both fluid and coagulated, which ran as far as the extremity of the fourth ventricle; the adjacent parts were softened; no appearance of adhesion of the coagula; there was a small spot of blood in one thalamus optici; corpora striata healthy; sinuses of the dura mater gorged with blood.

An instance of sanguineous effusion without the ventricle occurred recently. Mary Bignon, aged sixty-eight, a tall and powerful woman, was found in bed unusually late on the morning of May 9, and, on being roused, complained of headache; was rational in her answers; but, as she continued to sleep through the following day, she was brought here by her relatives on the morning of the 11th. Her symptoms on admission were as follows:—Countenance dusky, and void of expression; eyelids closed; no distortion of the features; answers questions readily when spoken to in a loud and sharp tone of voice, but relapses into a lethargic sleep; hemiplegia of the left side; pupils sluggish to the light, unequal in their size; pulse 84, small. She was actively treated by repeated doses of calomel and colocynth, and purgatives salines. (a) The head was shaved, and the course of the longitudinal sinus repeatedly blistered; cupping behind the right ear; turpentine enemata administered; and in the course of six days she was so far rallied as to promise to do well, apparently. Her back now sloughed from incontinence of urine, which supervened upon this temporary improvement, and she gradually sunk without a rational comatose symptoms, and died on exactly a fortnight after the attack.

Autopsy Eighteen Hours after Death.—The right hemisphere of the brain was flattened, the sulci small; there was a cavity capable of containing four or five ounces of fluid outside the right ventricle, the internal wall of which was formed by the external wall of the right lateral ventricle; this

cavity was full of semi-coagulated blood; much of the coagula adhered to the walls of this cavity by firm bands of semi-organized substance; the lateral ventricles contained a little clear serum; there was only slight disease of the arterial circle of Willis. All the other organs of the body were tolerably healthy, considering the age of the patient.

The following example of ramollissement at an early age elucidates the features of this cerebral lesion very well:—

Jas. Chaloner, twenty-six, labourer, admitted Feb. 17, with the following symptoms:—Countenance pale; a staring, vacant, and rather inanimate eye; features pinched; knitted brows; slight conjunctivitis of the left eye; on walking into the room it was observed that he dragged the right leg after him; when interrogated, he spoke in a slow manner, and with few words; does not feel when pinched in the right leg. Acknowledges that he has pain over the right eye; some cough and expectoration; pulse 96, full.

It was stated that he had suffered from a cough for three weeks past, which had brought on pain in the head. A week ago, on attempting to rise from his chair, he found he could not use the right leg; since which he has kept his bed.

Auscultation.—Dulness on percussion, and feeble respiration under both clavicles, but respiratory murmur healthy, as the ear descends to the lower lobes. C. c. ad 3xvj. nuchæ; hydr. c. cret. x., n. et m. Emp. canth. capiti.

The following note was made on the 21st:—

"Hemiplegia on the right side complete; lies in a drowsy, half-comatose state; acute conjunctivitis of the left eye, with purulent discharge; countenance quite inanimate, and more like a person in a narcotized sleep; irides act with a strong light; pulse 70, with some power; urine dribbles from him, ammoniacal; stomach rejects everything; respirations natural; sloughing of the nates; bowels confined two days. V. s. ad 3xvj. Emp. cantharidis; h. sen. co. 3ss.; c. tr. jalap., 3j.; dec. aloes co., 3ss. Enema tereb. vespero.

22. The serum of the blood was greenish, the crassamentum much buffed and cupped. Is now sensible, so as to put out his tongue. Pulse rose in frequency, but sunk in power after the bleeding. He rapidly sunk, and died on the morning of the 23rd, profusely sweating.

Autopsy Twenty-four Hours after Death.—*Head.*

—On stripping off the dura mater from the left hemisphere, a mass of small points, supposed to be, from their resemblance, the Pacchionian glands, was exposed over the edge and middle of this portion of the brain. On more minute inspection, however, this appearance turned out to be a series of small tubercles, which were beautifully seen when the arachnoid was carefully stripped off. They were opaque, and beneath them, and in their immediate neighbourhood, there was a debris or softening of the grey matter, but which was very vascular. The medullary substance did not appear to have suffered. In various parts, and around this spot especially, there were numerous points of tubercular deposition upon the arachnoid, or pia mater, and they were in various stages of softening; they had produced corresponding points of ulceration in the cineritious substance. Those that were softer than others, had evidently involved to a further extent the cerebral matter beneath it. The arachnoid in the median fissure, where it lies in contact with the falx, appeared of a straw colour, presenting the appearance of purulent matter beneath its surface; but this proved to be a series of the same tuberculous points, which were studded about this portion of the right hemisphere. In this half they had no where involved the cerebral substance. The general structure of the brain was otherwise very healthy and firm. *Chest.*—Lungs studded with tubercles, some of them being very advanced in the suppurative stage; they were general in both lungs, and the upper lobes were solid from the aggregation of several masses. The heart was natural in size, but the right ventricle composed more than one half of

the organ; the left ventricle was twice its natural thickness, but its capacity diminished. There was found a scrofulous tubercle in the posterior part of the right spermatic chord, and there was omental hernia on this side.

The next instance of ramollissement cerebri that I would add is unlike the preceding, inasmuch as it is not one arising from morbid deposition on the cerebral surface, but rather the result of an undue nutrition of the brain, in consequence of disease of the arterial system, and which was the immediate cause of death.

Eliza Robinson, aged sixty-five, admitted on February 26. Countenance dull and stupid; some expression of suffering in the knitted brows and slightly pinched features; iris of left eye more dilated than the right; answers incoherently; and it is evident that her statements must be taken with some caution. However, she owns that she has pain over the occiput, and numbness of the right arm and leg; can only lie on the right side for palpitation of the heart; deglutition impaired; the first sound of the heart is diminished, but there is great increase in the impulse.

States that she has been more or less subject to headache for three weeks past; but that three days ago, whilst at breakfast, was attacked with loss of consciousness, and on recovery found herself in bed with the above symptoms.

March 6. Was going on favourably; but this evening at eleven was suddenly attacked with convulsions and coma, and remained insensible until the 9th, when she died.

Autopsy Twenty-one Hours.—*Head.*—Veins turgid; on the upper part of each hemisphere, and especially on the right, there was distinct extravasation of blood beneath the arachnoid, from the vessels of the pia mater. This ecchymosis was of a purple colour, but, on exposure to the air, became, in half an hour, of a bright red; ventricles full of serum; hydatiform condition of the plexus choroides; the lower portions of the cerebellum were so soft that they broke down in the mere attempt to raise it: this pulpy substance was minutely studded with red points, and gave the whole structure the exact appearance of a mélange of mashed raspberries and cream.

Thorax.—The pericardium, to which externally was appended much fat, was filled with a firm coagulum of blood, which enveloped the whole heart, and slightly adhered to the auricles; it was taken out in one mass, of a bag-like form, and perfectly moulded. There was a small coagulum protruded into the layers of the pericardium, through a slit-like rent of the serous membrane, just at its point of reflection. It was supposed that the blood found its way from the aorta through this opening. This proved not to be the case. The walls of the left ventricle were thicker than natural, and on the edge of the mitral valve were a few hard, short excrescences. The aorta throughout was full of opaque, thickened, yellowish spots, some of them were distinctly bony; it was dilated in its coats. On its upper or convex part, and just before the primary branches are given off, there was a transverse crack or rent, upwards of one inch long, with clean edges, like a cut produced by a sharp knife. Rather lower down (and perhaps originally before the parts were pressed out of their natural position, just opposite) was seen the opening into the pericardium, as just mentioned. Between the two inner coats of the aorta and its outer or cellular coat, there was a large coagulum of blood; the small projecting clot formed a portion of a small coagulum lying between the serous and fibrous coats of the pericardium, and seemed to have got thither from the bag of the pericardium.

NAVAL APPOINTMENTS.—Surgeon: William M'Crea, to the Banana Islands Hospital.—Assistant-Surgeons: Robert Hastings, to the Cambrin; Henry F. Williams and Henry Slade, to the Banana Islands Hospital; J. W. Bradshaw, to the Fury; C. A. Robinson and J. M. Holman, to the Asia.

(a) This patient's body emitted the strong smell of misu so repeatedly noticed in cerebral diseases.

ON THE CAUSES OF FATALITY AFTER SEVERE SURGICAL OPERATIONS.

By HENRY SMITH, Esq., Surgeon,
Late House-Surgeon to King's College Hospital.

We are told that the use of the knife is one of the opprobria of surgery, and a proof of the insufficiency of the art of the surgeon. To a certain extent this is true; but, at the same time, the due and successful use of the knife, for the relief of those suffering from the incurable injuries and diseases to which the human frame is liable, proves how much can be effected by the skill of the surgeon, when rightly applied. It certainly is his highest privilege and consolation to be able to cure disease and relieve suffering by means afforded by his art, without having recourse to the formidable and hazardous use of the knife, and in many instances he can do this; but, when all his ordinary means have failed him, he still has a consolation in knowing that there is some other remedy in his power which he may employ for the salvation or relief of his patient, who, with destruction staring him in the face, is glad to submit to any measure which may afford him life or limb. That a consolation is it to feel that he can release from his sufferings one tortured by the agonies of stone in the bladder! What a gratification to know that he can relieve by a simple operation the poor wretch who is writhing under the dreadful agonies of a strangulated hernia, which, unless relieved, would lead him to a speedy and miserable death!

Bringing these things, then, before our minds, we cannot surely estimate too highly the operative department of surgery, and we cannot too highly prize those means (although as a last resource) we have in our power to apply for the benefit of our fellow-creatures. But, notwithstanding the value and efficacy of these means, we cannot shut our eyes to the fact that their employment is necessarily attended with much danger—in some instances with greater danger than that from which we are attempting to rescue the patient.

Every severe wound, whether accidentally produced or purposely made by the knife of the surgeon, is followed by more or less constitutional disturbance; and this is in proportion to the severity of the operation, and is much influenced by the constitution of the patient, and the particular circumstances under which he is placed. It is impossible for a surgeon to calculate previous to an operation all the subsequent effects it may produce, although he is aware that a certain amount of disturbance must follow.

A person undergoing a severe operation suffers in two ways—mentally and bodily. The anticipation of severe physical suffering, conjoined with a doubtful knowledge of the ultimate success of the operation, has a powerful influence on the minds of most persons: this consequently affects the body, and renders it more susceptible of painful impressions.

The employment of ether in surgical operations has, however, for the most part done away with the first anticipation; and its efficacy in preventing the sensation of pain, made known to the patient, removes from his mind that fear of suffering intense pain which is inseparable from the boldest of mankind; but, at the same time, it cannot cause his mind to be divested of a considerable amount of anxiety as to the termination of a severe and dangerous operation.

The effects of a severe operation will differ in different individuals in proportion to the state of health at the time, and the mental and physical endowments of their system. In some persons the constitutional symptoms will be correct in each of their stages to a great extent; in others we shall find hardly the least trace of severe constitutional disturbance: although in each case the operation may have been equally severe. This circumstance depends upon many circumstances over which the surgeon has little control. But yet, by a proper acquaintance with the causes which influence the results of severe operations, their fatality may be undoubtedly lessened; and this is being done day by day, and

has been done from centuries past: for who that knows the history of surgery will not say that vast improvement has been effected since the days when limbs were amputated with red-hot knives? Who can now see lithotomy performed without feeling that the palmy days of surgery have arrived, when he recollects the random thrusts of Frère Jacques? Even in later days what improvement has taken place in the treatment of aneurism! It must be admitted that all the various improvements in the manner of performing operations have a great share in modifying their subsequent effects, independent of a knowledge of the other causes which bring about unfavourable results. The influence of the mind has undoubtedly a great deal to do with the result of an operation. There are few persons about to undergo a severe and dangerous operation who can so command their minds as not to feel some dread. This is felt when it is known that pain alone will be the effect; but when it is known that the result may be attended with death, it requires the greatest philosophy for an ordinary mind so to screw itself up as not to feel some apprehension.

Fear is a depressing passion, and not only fear but that which is akin to it—an unhealthy concentration of the mind upon some disagreeable subject. These depressing influences exert themselves upon the heart, which becomes weakened in its action, also upon the functions of digestion and assimilation. If they last only a short time, their effects are merely transient and cause little mischief, but when they are constant the vital powers become powerfully affected. Thus a person who has been brooding over an anticipated operation for some days or weeks, gets into such a state of mind that he becomes as it were a monomaniac, and will either not allow it to be performed when the time arrives, or will express a conviction that it will be fatal; and this so depresses the physical powers that that salutary reaction which follows upon a severe operation does not take place, and he dies the victim of his own mental uneasiness. Every one who has watched the minutiae of his profession must have noticed that an intense anxiety on the part of the patient, or a conviction that his wounds will be fatal, is really a bad and fatal sign. The following is a good example of this kind: I quote it from Mr. Travers's work on "Constitutional Irritation":—"A lady, who concurring, as a point of duty, with the advice of her surgeons, reluctantly submitted to the removal of a small tumour in her breast, unexpectedly, and without any apparent cause, died on the following morning of the operation. It was then for the first time ascertained that she had prognosticated her death; and the impression that she should not survive had taken so strong a possession of her mind, that her minutest household arrangements were preconcerted, as appeared by the papers found in her cabinet."

It may be presumed, then, that an uneasy and anxious state of the mind has considerable influence over the result of an operation.

On the other hand, a firm and quiet state of mind has the effect of keeping the vital powers in healthy action, and thus greatly favours a safe termination. There are many who possess this firm state of mind, and a total carelessness about the pain of operation. I have known a man to make ludicrous gestures during an amputation of the leg, and I have seen a tumour weighing seven or eight pounds dissected from a man's back without the least wincing or evidence of pain.

The state of bodily health has a great influence on the result of an operation. Thus, we find that those who are in a moderate state of health suffer least. If the patient has been labouring under a long and painful disease which has lowered his constitutional powers, there will be less chance of his recovery than if the disease had existed only a short time, and had made less inroads on his frame. But, on the other hand, if he is in a state of rude health prior to the injury which may require an operation, he will be in an unfavourable condition to undergo an operation.

John Hunter has remarked, that "those who live above par are extremely liable to sink when attacked by disease or injury, for, as they are habitually at the full stretch of living, their powers cannot be exerted further to meet any casual emergency." There are some states of the system which, although to a casual observer may appear to be healthy, are not so in reality; I allude to those unnatural conditions which are produced by taking large quantities of malt liquor and spirits, examples of which are seen in brewers and coalheavers. These persons look robust and healthy, but they are the very worst subjects for an injury or operation. A stout healthy-looking man was brought into King's College Hospital, he having received a lacerated wound of the integuments near the knee. He was intoxicated when admitted. Notwithstanding extreme care, an immense amount of constitutional disturbance arose, with extreme exhaustion. The wound was attacked with frightful inflammation and sloughing, and soon involved the joint, and ultimately caused dislocation of the femur; and the patient, from being a stout man, was, in a short time, reduced to a skeleton, and was only kept alive by a large amount of his ordinary stimuli. This poor fellow told me he was in the habit of taking daily two or three gallons of beer. Such cases as this are particularly unfavourable for an operation, and especially for recent injuries, such as compound fractures.

If organic disease exists to any extent in any of the viscera, the chances of a patient doing well after an operation are much lessened; in fact, as a general rule (to which, of course, there are exceptions), operations should not be performed in such cases; but, sometimes the symptoms of the disease which has lain dormant before, and has not excited the attention of the surgeon, have rapidly developed themselves after the operation has been performed, and quickly carried him off.

A nervous and irritable state of body is unfavourable: there is fear of tetanus or traumatic delirium arising. I have lately seen one or two instances, which I shall more particularly mention, where death appeared to be owing chiefly to this irritable state of the system.

The state of the atmosphere is another cause which must greatly influence the results of surgical operations. Thus it is known that operations are less fatal in provincial hospitals than in the hospitals of large cities, where they are more crowded and less better ventilated, and, consequently, the air more tainted. When the air is close and impure, erysipelas, local inflammations, and irritative fever are more likely to show themselves after operations.

These are the chief circumstances which affect the results of operations. It is necessary for the surgeon to be well acquainted with these circumstances, although he is not able to control all of them, yet he may do so in a great measure; and here he will show his skill in his art, for it must be borne in mind that the good operative surgeon shines not only in using the knife well, but in knowing when to operate, and in being able to understand those particular circumstances which have so much influence over his patients, and to bring them under his control. To quote the words of Mr. Travers, "The habits of long indisposition are fully as important to be known as the habits of health, perhaps, more so. It is impossible for an operating surgeon to do justice to his patient or himself, who is indifferent to particulars, of which his ignorance may be disadvantageous. As the most successful artists are studious of opportunities to become familiar with the expression they are about to portray, a surgeon should apply himself to the character of the individual who is to be the subject of an important operation. Such a method of proceeding will not only enable him to exercise a sound discretion in the selection of his cases, and the time and mode of his operation, but will bring him to the bedside of his patient, at its conclusion, on the vantage-ground of mutual confidence. The practice of performing a tedious operation, and leaving the after-treatment to

others, has, in my knowledge, repeatedly proved disastrous. The medical treatment—a duty not less responsible than the operation—belongs to the surgeon; and, indeed, to be employed merely as a handcraftsman conveys an imputation at which the dignity of a scientific mind revolts."

We shall proceed now to consider more particularly the causes which render operations so fatal; for that they do prove very fatal nobody who has seen much of them can deny. He who has taken the trouble to look over the records of operative surgery, both at home and abroad, in civil and military practice, is well aware how often the best efforts of the surgeon have been baffled by unfortunate accidents. I shall select for consideration some of the most serious operations the surgeon has to perform; and shall confine myself almost entirely to those cases which I have witnessed, occasionally borrowing from other sources, as I think suited to the subject.

Out of sixty-one cases—all of which were capital operations, or operations of a very severe nature, and most of which I witnessed, or assisted at, both during the operation and in the after-treatment—I find that the deaths amounted to twenty, exactly one-third of the whole number. The mortality would appear to a careless observer at first sight large, but it is not so large in reality, when we consider that these operations were all of a very severe nature, and of a mixed character. Thus, these sixty-one comprise the following:—Five ligature of large arteries; sixteen cases of lithotomy; nineteen amputations; ten cases of hernia; six excisions of large bones and joints; five cases of extirpation of the mamma. The mortality in each case was as follows:—Of the five cases of ligature of arteries, four died; in the sixteen cases of lithotomy there were four deaths; of the nineteen amputations six proved fatal; six out of ten cases of hernia died; one of the five who had the mamma removed died; the six cases of excisions were successful.

Now, let us inquire into the cause of death in each case, and we will begin with the operations on arteries. The first on my list was a case of ligature of the first part of the subclavian, for aneurism. The operation was performed by Mr. Partridge, and, as I understand from eyewitnesses, in a manner which reflected great credit on the knowledge of anatomy which my late distinguished teacher is known to possess. This patient, immediately after the operation, had symptoms referable to the stomach; he felt sick and vomited; soon afterwards lost some blood from a divided vein; pain at the stomach then became a prominent symptom, in addition to this, a distressing sense of thirst was felt. With these symptoms continuing upon him, the organs of respiration became embarrassed, and he sank on the fourth day. On a *post-mortem* examination some pleurisy was found to exist. The particulars of this case will be found in the *Lancet* for 1841.

The second fatal case was one in which Mr. Ferguson placed a ligature on the carotid, for aneurism of the innominate, according to the method advised by Brasdor and Wardrop. This patient lived for several days, but finally sank, with symptoms referable to the respiratory organs, which, after death, were found gorged and inflamed. The case was published in "The Edinburgh Monthly Medical Journal" for 1841.

The third case was ligature of the external iliac, for aneurism. This patient was in a bad state of health at the time he was operated upon. He did not suffer more than usual from the operation, but irritative fever produced by an unhealthy and hidden erysipelas attack carried him off on the sixth day. Some slight signs of peritonitis were found; the peritoneum had been opened unintentionally during the operation.

The fourth case was one in which a ligature was placed on the external iliac, for secondary hemorrhage from the femoral artery. The patient lived for many days after the operation, but hemorrhage again occurred, and finally gangrene of the limb below, which caused

Here are four fatal cases; and let us examine more closely the causes of death in these, and in cases generally, where arteries are tied.

In the two first, death was mainly owing to causes dependent upon the site of the operation. The first patient suffered chiefly from irritation of the stomach, and then the pulmonary apparatus.

The second died with symptoms of inflammation of the lungs. Are these symptoms similar to what are usually noticed after ligature of arteries in the neck; and if so, how are they caused?

It has been noticed frequently, that operations upon arteries in the neck have been followed by symptoms of inflammation of the chest, and irritation of the stomach. Professor Miller, of Edinburgh, has written a paper, some few years since, in which he shows that most of these operations prove fatal in consequence of supervening inflammation of the chest; and the fact can be easily explained. In operations upon the subclavian and carotid arteries, the large nerves which supply the breathing apparatus and the stomach can scarcely ever, from their proximity to these vessels, escape some injury more or less severe; and we have reason to apprehend that irritation of a nerve may cause irritation and subsequent inflammation in the parts to which it is distributed. Again, the pleura is in close contact with the subclavian, so that it is liable to be injured, or at all events it is exposed to a participation in the inflammation which is set up in the wound.

It is highly probable that the first of these patients died from irritation of the pneumogastric nerve, which irritation was propagated to the stomach and lungs, causing vomiting, pain, and difficulty of breathing. In the second patient the lungs alone were affected. In very many of the unsuccessful cases of ligature of arteries in the neck, these symptoms have preceded the fatal event. In Mr. Colles's case of ligature of the first part of the subclavian, the patient died on the tenth day, with symptoms of strangling and pain about the heart; here the pleura was wounded during the operation, but this probably had nothing to do with the death of the patient. The sensation of strangling and pain about the heart was probably due to irritation of the phrenic nerve, which is liable to injury in this hazardous and, as yet, totally unsuccessful operation.

(To be continued.)

PRACTICAL OBSERVATIONS RELATIVE TO THE MANAGEMENT OF THE INSANE.

By WILLIAM SMITH, M.R.C.S.E.

Formerly House-Surgeon to the Lincoln Lunatic Asylum, and afterwards to the County Hospital at Lincoln.

The rapid increase of insanity, and the number of new lunatic hospitals demanded within the last few years (some of them now in course of erection in different counties in England), are strong proofs of the importance of this branch of medical science.

If our large public asylums were capable of containing all the unfortunate persons labouring under mental derangement, their condition and management need not occasion much anxiety. The Governors of the Lincoln Asylum, in their Fifth Report, have truly remarked, "It may, indeed, be laid down as a principle in human nature, which experience will amply confirm, that no institution of this sort can be considered safe in its management, where the managers are not subject to some eye unconnected with the government of the institution itself. The public eye and public opinion have in all cases been found the most efficient; and the original rules of this institution, wisely and humanely acting upon this principle, court and avow a system of public inspection under due regulation."

As regards the public lunatic hospitals of England, the principle is undoubtedly carried out; and to this free admission of the public eye,

I mainly attribute their superiority over the licensed houses or private madhouses.

And yet, how many thousands of our fellow-creatures are at the present moment immured in these private asylums! That there are many gentlemen, of extensive acquirements and strict integrity, engaged in the management of the insane, I will most cheerfully admit; but that numbers of persons in the neighbourhood of London (of no education or next to none) are speculating in the infirmities of their fellow-creatures, the numerous private licensed houses will abundantly demonstrate.

The strongest recommendation in favour of public asylums (or, as we may very properly term them, hospitals for the insane) is the free admission of the public eye; and, if we consider the position of the lunatic, we must admit this to be a powerful safeguard against abuse. The Fourteenth Report of the Glasgow Lunatic Asylum has some very sound remarks on this subject:—"The regulations of a lunatic asylum, while they prohibit unnecessary publicity, ought most strictly to guard against improper concealments. The position of lunatics in an asylum differs widely, in regard to some important circumstances, from that of persons placed in any other public institution, for cure or confinement. The lunatic is an incompetent person of what passes around him; he is often insensible of his own degradations and sufferings; he is not believed even when he complains on just grounds; and his report is least of all to be credited when his uncleanly habits, bewilderment, and fury render him most liable to suffer from neglect and cruelty; or when, perhaps, sinking under the extreme violence of his lamentable malady, his case demands the utmost tenderness and care. He may be regularly visited by the physician, and occasionally by affectionate relatives; but, during by far the greater part of his time, his treatment can be known only to two individuals—the keeper who executes, and the person whose duty it is to superintend, the treatment. Let a compact once be formed between these two persons, and an impenetrable veil may be thrown over the grossest abuses." Now, that these remarks are based upon truth, any person at all conversant with the interior of a lunatic establishment must at once admit; if, however, they are applicable to a public lunatic hospital, by how much is the evil increased in the case of a private asylum! Here, the proprietor (frequently not a medical man) has every control over the attendants: he pays them their wages, and can discharge them at a minute's warning; the lunatic in the private asylum is also deprived of another great source of protection from abuse—I mean the free admission of the public eye. The learned commissioners in lunacy certainly make their visits half-yearly; but when we recollect that nearly one half of that body are barristers very learned in the law, whilst the doctors (excepting, perhaps, Dr. Prochard) are none of them practically acquainted with the management of a lunatic hospital, we cannot imagine them to be very skilful at discovering abuses; in truth, we have one lamentable instance of their puerile conduct or gross apathy, in the case of the ever-memorable Haydock-lodge Asylum, where, under the humane control of an ex-assistant poor-law commissioner (Mr. Charles Mott), the mortality actually reached thirty per cent. So much for the zeal and diligence of the learned commissioners. But, if I am not mistaken in my estimate of human nature, lunatics will still continue to suffer from gross neglect and the brutal tyranny of uneducated keepers, until private licensed houses are placed under different management; the lunacy commission, to be effective, must be entirely remodelled; in place of physicians verging towards second childhood, we must have men in the prime of life, with their intellects in a vigorous state; they must be selected from men who have ruled over such establishments as Hanwell, Lancaster, Glasgow, or Northampton. The present commission, as a means of detecting abuse, is little better than a

a solemn mockery, and its public acts convey the impression of an incipient dementia.

In place of originating grand improvements in the management of the insane, the whole efforts of the commissioners hitherto have had a contrary tendency: witness their puerile and impotent attacks upon the management of Hanwell and Lincoln—attacks which have been gallantly resisted by the governors of those establishments; their exertions in retarding the efforts of scientific individuals remind one of the break occasionally applied to check the velocity of a railway carriage.

In the case of the "abolition of mechanical restraint," one of the greatest boons ever yet conferred upon the lunatic, these zealous individuals, with a perseverance "worthy of a better cause," threw all their influence into the adverse scale, and joined heart and soul with the advocates of mechanical restraint—the keepers of the private madhouses, *et hoc genus omne*. That my assertion is correct, I need only refer my readers to their solitary official report to the Lord Chancellor, wherein every argument that could be adduced is brought to bear against "the insane system." And yet these are the men whom Dr. Winkle, of the Warneford Asylum, is bespattering with praise: "an Anthony worthy of such a Caesar!"

The battle of non-restraint has been fairly fought, and, notwithstanding all the exertions of its opponents (backed by those who had a sordid interest in opposing its onward progress), it has triumphed in every institution which has given it a fair trial. Probably, in no place were its merits more severely tested than at Lincoln—its original birthplace. Like all great improvements, whether in medical science or the arts, it had to encounter numerous difficulties; parties, jealous that others should know something more than themselves, fiercely denounced it as a Utopian scheme; others adopted the practice, but, strangely enough, contested the theory. To Dr. Conolly undoubtedly belongs the merit of having successfully carried out the system in one of the largest lunatic hospitals in the world. Much mischief, however, may undoubtedly occur if the non-restraint system be adopted without first securing proper means of occupation and amusement for the patients; and on this score, viz., employment, I am of opinion that Lincoln is behind Wakefield, Nottingham, and other places, where restraint (to a small extent) is still employed. The General Report of the Royal Hospital of Bethlem for 1844, page 49, in speaking of restraint, contains the following remarks:—

"Personal restraint has been reduced to one-tenth of what it was six years ago; and it is most gratifying to be able to state, that it has been reduced to one-half of what it was in 1843. The following returns show the average weekly number of patients in restraint during the last six years:—1839, 11 35-52; 1840, 13 20-52; 1841, 9; 1842, 3; 1843, 8 4-52; 1844, 1 35-52."

"It is almost unnecessary to say that restraint has diminished just as the means of occupation and amusement have been increased, and that without such means and appliances it would be injudicious to attempt to dispense with mechanical restraint; and, in judging of other institutions, this ought to be carefully borne in mind, to prevent a hasty and, unintentionally, unjust conclusion."—King-street, Belper, Aug. 26.

ON THE CONSTRUCTION OF HOUSES FOR THE RECEPTION OF THE DEAD; AND ON THE MEANS TO BE USED FOR THE RECOVERY OF THOSE WHO ARE ONLY IN TRANCES OR FITS, OR IN WHOM LIFE IS ONLY IMPASSIVE.

By ROBERT BRANDON, Esq.,
Great Russell-street, Bloomsbury.

DUBITUM VITÆ REFUGIUM; OR, ASYLUM FOR DOUBTFUL LIFE.

The building should be large enough to provide means for resuscitation, and room enough for the deposition of bodies when epidemics are prevalent. There should be hot-baths, for these are often enough to elicit the vital spark; and a kitchen there should be, to prepare nourish-

ment for those who are recovered, and for the porter and other officers who would live on the building. The room for the deposit of the bodies should communicate with the porter's room by means of a glass door, and every body should have a wire fixed to the feet and hands, in communication with a bell, which bell must ring in the porter's room, in order to warn him, should there be any motion in those thought to be dead. There should be men and women on the premises to use friction, a galvanic machine, and the implements necessary for transfusion and artificial respiration. As the usual and accepted signs of death are not signs to be relied on, so is decomposition a true sign, and none should be buried until this be present; but as the presence of decomposed animal matter would be injurious not only to the inmates of houses, but to the surrounding inhabitants, and as it is inconvenient to the poor man who has but one room to keep a body in that room where he and his family eat, drink, and sleep, asylums for the reception of those thought to be dead should be constructed, and are absolutely necessary. Nor is it enough to wait for decomposition, but we should endeavour to prevent this by endeavouring to restore vitality by means of hot-baths, external heat, artificial respiration, galvanism, or transfusion—the first of these is oftentimes enough. Now, I think it probable that many persons would be recovered, thought to be dead, for, out of a certain number of those reputed dead, a certain number have recovered—some by the sticking of the pins into them which fixed the shrouds, some under the surgeon's knife, some from delays in the burial, and others from the accidental overturning of the coffins, as we learn from a paper published some time since, on premature burials. Some time since a woman was kept above ground for a considerable time, as medical men could not decide if she were dead or no; and at Constantinople a sailor, the other day, was attacked with apoplexy, and a vein was opened in his arm; no blood came, and the man was thought to be dead, but on the road to the grave, blood began to flow, and the supposed dead man recovered. There is now living, in Brussels, a man who escaped from the grave; and another built a house at Cologne to commemorate his escape. These cases will be enough to show that we have no certain sign of death but decomposition; and, if this be true, we must have asylums for the reception of bodies previous to decomposition, and for the application of means which can do no harm, and may do much good, such as those before indicated. Medical men think that the absence of respiration, and want of heart's action, with loss of motion and sensation, are signs of death; but this is not the case, for many bodies which have been drowned have all these signs present, and yet recover. Again, infants are often born without any action of the heart or lungs, and yet are recovered by very simple means, such as the hot-bath; and I myself have recovered persons by stimulants who were thought to be dead. Many may be recovered by transfusion (first introduced into this country by the celebrated Dr. Blundell) when the heart still palpitates, but the brain is insensible; or by stimulants given at that period; or by hot-bath, and the external application of heat by galvanism, where other means have failed, and these can do no harm. Since the brain is insensible there can be no suffering; and many lives will be saved by perseverance, and the skillful application of means which have succeeded in isolated cases. Buildings for the reception of those thought to be dead should be placed in cemeteries. I divide life into two active and passive. Life is active when man is in the enjoyment of all his faculties, intellectual and moral; when the various organs necessary for circulation and respiration are in play; when there is sensation, perception, and motion; and when the sphincters are not relaxed. Passive life is that state hitherto called death; but, according to me, death is decomposition. Nor should we despair at any period previous to this, since we can give motion by galvanism; blood by transfusion; respiration by artificial respiration; heat by this and the external

application of caloric; and by stimulants we can keep up that action which has been excited by other means. Nor must we despair if we do not at once succeed in our endeavours to recall life, for perseverance often accomplishes that which at first sight seems impossible. Men have recovered from simulated death after being in the sea twenty minutes, and I see no reason why after disease men may not also be recovered from a state resembling death. Many are only in fainting fits, some are in trances, who are left as dead; and graves have been opened when the buried man has been found to have eaten portions of his own flesh, which, of course, he could not have done unless recovery had taken place. How horrible to think that we may awake up in our graves tormented with the pangs of hunger, unable scarce to breathe, and, finding all escape from our narrow cell impossible, the prisoner in his grave has nought to do but to commend his soul afresh to his Maker, and lay himself down to die! May not much of this be prevented by asylums for doubtful life, by the application of reagents, and by building vaults in our cemeteries instead of graves? I earnestly hope that the day has arrived when we see these things in the proper light; when our churchyards will be no longer overloaded with the remains of those who, perhaps, might have lived had they been left a little longer above ground—had they been transfused, or even buried in vaults instead of graves, with a guardian to watch over their mortal remains! In order to make myself more clearly understood, and to explain my own peculiar views, I will state that we cannot give life, but we can supply electricity to human and animal bodies, and by it produce many of the phenomena of life; neither can we make electricity, but only render that evident which was before latent, as in a piece of sealing-wax the electricity may be made evident by friction, and attraction and repulsion may be thus produced. The causes of friction in the human body are the various motions which take place between the different organs, between these and their containing cavities, and between the organs and the blood contained within them; between the veins and their blood, between the arteries and the blood, and between these and the muscles. In order to recall life in doubtful cases, you must apply electricity, and thus recall the natural action of organs necessary for rendering that life active which was, may be, only passive. Thus, life may exist but not be evident; but the non-evidence of life is no proof of death, as many have been recovered in whom life was only latent—in whom there was no action of the heart, no respiration, no motion, no sensation. This has happened after drowning, in infants born asphyxiated, in women after flooding, and would happen much more often were the proper means applied in all cases to recall life, and to ascertain those who may be recoverable. Simple inspection is not enough to decide if a man be dead or not, because persons are often only in trances or fainting fits when they are thought to be dead; and I wish to insist on the fact that there is no sign of death but decomposition, and that, therefore, none should be buried until this sign be present, nor until an attestation of the presence of decomposition be given by some surgeon. I believe that most lives would be saved, in approaching death, when the heart has not yet ceased to palpitate, but the brain is insensible; it is at this moment that transfusion would be a very powerful means of cure; and, in order to satisfy ourselves on this point, we have only to read a description of the effects of the injection of blood into the veins of animals. Many persons are predisposed to death by too active treatment, by the loss of blood, by the careless administration of drastic purgatives; and to these transfusion would offer great means for recovery. Dr. Blundell should ever live in the hearts of his countrymen, for he has introduced into this country a remedy the usefulness of which is not sufficiently known, and which, I think, would be of use not only in approaching dissolution and in flooding, but also in typhus and many diseases of debility.

PROGRESS OF MEDICAL SCIENCE

ACADEMY OF SCIENCES.

Meeting of Aug. 30; M. BRONGNIART in the Chair.

INTERNAL INHALATIONS.—M. Sédillot, of Strasbourg, forwarded to the academy the detailed account of fifty important operations performed by him during the insensibility produced by ether. These cases confirmed the observations previously made by M. Sédillot, that no subjects were refractory to the influence of the inhalation, although the period necessary for the establishment of loss of consciousness varied with each subject. In some of his operations, by intermittent inhalations, M. Sédillot caused insensibility to last as much as one hour and a half.

ACADEMY OF MEDICINE.

Meeting of Aug. 31; M. BÉGIN in the Chair.

M. Hamont read a paper relative to an epidemic of typhus, which decimated the cattle in Egypt during the years 1841-42-43. The disease was brought into Egypt by a packet, which imported from Caramania two hundred oxen. The neglect of proper measures of quarantine, according to Dr. Hamont, caused the disease to be propagated on shore, and in less than three years destroyed 350,000 oxen.

LITHOTRITY AND CYSTOMY.—(Adjourned Debate).—M. Velpeau acknowledged that he hardly knew how the present discussion had originated. He had endeavoured to ascertain how far lithotripsy had been useful to humanity, and had found that question very difficult to solve. It would be necessary, in order to come to some positive conclusion, to be in possession of two or three thousand cases of calculus treated by cystotomy, and of an equal number operated by lithotripsy. Even if such a statistical table could be brought forward, it would be insufficient, because lithotripsy was not applicable to all concretions; the cases must be chosen ones; hence the impossibility of comparing fairly the results of the two methods. Examining M. Civiale's own tables, M. Velpeau found in a first series 282 cases, 70 of which terminated fatally. In a second, out of 83 patients, 30 only were alive at the end of one year. These were frightful results, which M. Velpeau could not reconcile with the assertion made by M. Civiale, that he cured 98 out of 100 cases. M. Civiale's method of establishing his statistical tables was the only explanation of these fabulous results. When one of his operated patients died of peritonitis, of cystitis, of pleurisy, M. Civiale asserted that death had not been the consequence of the operation, and struck the case off his list. This was not a fair manner of proceeding, neither was it just, although it might be convenient to M. Civiale, to assert, as frequently as he did, that he (M. Civiale) alone knew how to perform lithotriptic operations with proper ability, and that the occasional failure of his method was always to be referred to the incapacity of the operator. All this was not right, and, in order to carry conviction into inquiring minds, it was necessary that M. Civiale should permit a close and searching examination of his cases: this M. Velpeau intended to do at the next meeting of the academy.—Adjourned at five o'clock.

HEMORRHAGE FROM THE UMBILICUS.

In a former communication we reported a case of hemorrhage from the umbilicus, which, various methods having failed, was arrested by ligature. (See vol. 18, page 116.) We find in the "Journal des Connaissances Médico-Chirurgicales," a case of similar nature, and, as the accident is a comparatively rare one, we extract from that journal the following details:—

"On June 17, 1847, Dr. Jeunin was summoned to attend an infant, aged seven days, who was suffering from umbilical hemorrhage. The fluids had fallen away during the preceding night, and in the morning the loss of blood had been noticed, but when towards noon the child

was undressed, it was found bathing in its blood. Various anti-hemorrhagic remedies, such as vinegar and water, tincture, &c., were at once employed, but without success. Dr. Jeunin again tried the vinegar, compression, &c., and the hemorrhage continuing, was induced to cauterize the scar with nitrate of silver. Still the blood continued to flow abundantly. Cauterization with the actual cautery was resorted to, and failed signally in arresting the hemorrhage, although two red-hot rods of iron were extinguished in the wound. At last ligature was thought of: a common sewing needle was passed through the tubercle, and a circular ligature placed beneath it. The discharge of blood immediately ceased: the needle fell away four days afterwards, and the child recovered.

NITRATE OF SILVER IN HOOPING-COUGH.—In whooping-cough, Professor Trousseau recommends the exhibition of nitrate of silver. It seems to diminish considerably the violence and frequency of the paroxysms, but does not appear to shorten materially the duration of the disease. To a child, aged fifteen months, Professor Trousseau gives the medicine in the following shape:—R. Aq. destill. 3j.; syrapi, 3ss.; argenti nitratie, gr. 1-5th. Capiat cochleare unum min. q. q. horâ.

VAGINITIS. BY DRs. BOYS DE LOURY AND COSTILHNE.

The principal symptoms of vaginitis in its acute state are pruritus and heat of the affected part, tumefaction of the sexual organs, a sensation of stricture of the vagina, redness of its folds, and occasional erosions of the mucous membrane. The pus is at first very fetid, but soon loses its offensive odour. When inflammation occupies the superior part, or the entire cavity of the vagina, the os tincæ acquires a brownish hue, and becomes very painful. Chronic discharges are frequently not contagious, but may become so under the influence of stimulants, or rather the fresh irritation which stimulants produce. As to granular vaginitis, which deserves more properly the name of papillary vaginitis, it is met with during pregnancy in nineteen cases out of twenty, and is characterized by small round elevations of a dark red colour, and perfectly indolent; the discharge is white or yellowish, and tolerably abundant. This disease, observable during the last months of gestation, resists all methods of treatment, but yields spontaneously after parturition. M. Boys de Loury asserts that vaginitis is common in young persons, and even in children of six or seven years; and that this circumstance should induce surgeons to be on their guard when called upon to decide before a magistrate upon the nature of a discharge existing in a child. It appears that little girls, of eight or ten, are not infrequently tutored to play the part of victims, and that a mistake would readily be committed if this fact was lost sight of. The symptoms by which this form of infantile vaginitis may be distinguished from the effects of violence are the integrity of the hymeneal membranes, and the absence of dilatation of the vagina; the parts are red and inflamed, and the purulent discharge is, in reality, much more abundant than in the inflammation which follows violence.

The treatment which the authors recommend in vaginitis consists of antiphlogistic measures at first, almost entirely of a local nature, and of stringent injections when the disease has lost its first violence. They agree with Dr. Ricord in the inutility of cubebs or of the balsam of copaiba for the treatment of the gonorrhœa of women. These two substances, says Dr. Ricord, relieve gonorrhœal discharges by their local action on the urethra, an assertion which is supported by the following interesting case:—A man was admitted into the Hôpital du Midi labouring under gonorrhœa during the year 1841. He presented a fistula of the urethra at two inches from the meatus; this accidental orifice was the result of gangrene of the part, produced at the age of seven by a ligature placed by himself around the penis in order to prevent involuntary emission of urine during the night, an occurrence which ex-

posed the child to a severe whipping in the morning. When the patient was received in hospital a double discharge existed, from the meatus and from the fistular orifice, through which all the urine was emitted. The disease was treated by the exhibition of cubeb-pepper, and the discharge of the fistular passage alone was arrested. Injections of nitrate of silver were afterwards necessary for the cure of the running from the meatus.

CONVULSIONS OF CHILDREN, BY M. GUERSANT, M.D.

—Convulsions may be divided into three varieties: idiopathic, symptomatic, and sympathetic. The first form occurs suddenly, and attacks the infant in the most flourishing state of health; and disappears suddenly, leaving no other trace of its existence than slight and temporary exhaustion. The convulsions, which are symptomatic of a more or less considerable alteration of the nervous centres, are preceded by disturbances of the functions of innervation, headache, increased sensibility, and often febrile excitement. When the convulsions appear the head is hot and painful, the cry is violent, and vomiting is observed. These attacks persist for several hours or days, with remissions, during which the intensity of spasmodic contraction diminishes; the child not recovering, however, completely, the exercise of its cerebral functions. Sympathetic convulsions are always connected with disturbance of an important organ, and more particularly of the stomach. M. Guersant has seen convulsions last for several days, and yield only to the rejection from the stomach after that period of undigested food. For the treatment of convulsions M. Guersant is of opinion that antiphlogistics have been praised beyond their deserts. If, however, the child is vigorous, the countenance injected, or asphyxia imminent, leeches may be applied with advantage. Compression of the carotid arteries—a remedy recommended by Professor Trousseau—is principally applicable to the congestive form, and to those convulsions which occupy only one side of the body. The artery of the side which is not convulsed is that which should be pressed upon, with the thumb or the index and medius fingers united, the palm of the hand being placed in such a manner as to avoid any pressure on the trachea. The result is often instantaneous, but if after a few minutes the convulsions are not arrested, the method must be abandoned. Blistering and mustard poultices on various parts of the skin, purgatives internally—calomel and jalap, for instance—are very generally recommended; but M. Guersant has not much confidence in their efficacy. Cold applications to the head, on the contrary, are most efficient, and amongst the more advantageous we may mention cold affusions and irrigations, particularly upon the fontanelle in very young children. Sometimes, however, convulsions are accompanied with a refrigeration of the surface of the body, by which cold irrigations would be rendered a highly dangerous plan of treatment. Amongst antispasmodics, M. Guersant prefers the oxide of zinc, alone or combined with hyoscyamus; musk, ether, valerian, and assafoetida have also been used, the two latter in injections, on account of their taste and odour, which cause them to be taken with difficulty, particularly by children. The oxide of zinc M. Guersant exhibits in doses, gradually increasing, of from one to twenty grains daily, in powders with sugar, or in a single draught.

The executioner at Bourges has been recently condemned for illegal practice of medicine. The executioner of Nantes, also, not satisfied with the proceeds of his art, and doubtless considering himself qualified for the practice of surgery, had for several years derived a handsome competence from the exercise of medicine. The tribunal of Nantes condemned the aspiring headman to fifteen francs fine.

D. MCCARTHY, D.M.P.

Treatment of Fingers of the Anus.—M. Diday recommends the patient to apply to the nose,

night and morning, with the end of the finger, a portion of ointment, about the size of a cherry-stone, composed as follows:—Axungie 15 grammes, tannin 1 gramme, increasing the portion of tannin gradually to three grammes or more, according to its effect on the sensibility of the part. To apply it efficiently, the patient should push his finger as far as possible without forcing the sphincter, and there leave the ointment. Where fissures are situated higher, a solution of tannin may be injected into the rectum with a small syringe. The quantity of liquid introduced should be as small possible, in order that it may be retained for some time. In both cases the patient should experience some degree of heat, and smarting continues for some time after the application.

Aneurism by Anastomosis in the Anterior Naris Cured by the Actual Cautery.—The patient was a woman, thirty years of age, admitted into Stevens's Hospital under Dr. Wilmot. When ten years of age, after leaping from a height she was seized with a profuse discharge of blood from the left nostril, which occurred several times for a week, and was then stopped. About four years and a half afterwards a tumour, the size of a pea, was observed on the inside of the left ala nasi. It was attended with pain which extended over the left side of the nose, with a sense of fullness about the side of the head, the tumour increasing so as to attract attention. When admitted into the hospital it was about the size of a small olive, attached to the inner surface of the ala of the left nostril. It was of a dark blue colour, soft, smooth, and equal on its surface; and upon pressing it an obscure pulsation could be felt. The coronal artery of the lip and the lateralis nasi pulsed strongly, and appeared to feed the tumour. She remained in the hospital but a short time, but returned in four months, during which time the tumour had increased in size, and the pulsation was now very evident. It was at first punctured with a cataract needle, and through the puncture a small probe was introduced coated with nitrate of silver. A rapid flow of blood followed each operation, but was stopped by pressure. The caustic was then applied three or four times, and during the intervals astringent lotions and pressure were employed. This produced a temporary reduction of the tumour, which, however, eventually appeared to become larger, and there was, with headache, a throbbing over the left side of the face. She again left the hospital for half a year, when, on her return the tumour had considerably increased, and had assumed a round form, filling the anterior cavity of the left nostril, and extending a little beyond its margin. All the circumjacent arteries were enlarged, the lateralis nasi to the size of a crow quill, and pressure on this and the coronary artery commanded the pulsation in the tumour. It was now resolved to perforate it with the actual cautery. The operation consisted in penetrating the sack in two distinct places with a nail-shaped iron cautery. This was repeated six times, at intervals of fourteen days. After each application the tumour swelled, became painful, and in about three days pus was observed to escape through the openings. At the end of three months she was discharged from the hospital quite well, there being no trace of the tumour, the lateralis nasi artery could not be felt, and the other arteries were restored to their natural size.

Carcinoma of the External Surface of the Stomach.—"Deposit of cancerous matter," observes Dr. Alderson, "may take place either beneath or upon the serous membrane covering the stomach, and may vary in consistence. As the deposit increases it gives rise to inflammatory products, by which the contiguous viscera are glued together, and at length the stomach, liver, pancreas, omentum, and more or less of the intestines, are united in a mixed mass of cancerous deposit and inflammatory products. In the latter stages of the disease ulceration finds its way into the duodenum, colon, or stomach; jaundice is sometimes a symptom, and the liver is generally affected by secondary deposit. Among the

earliest symptoms there is constipation, with some amount of pain. The tongue is clean, appetite moderate, with thirst. In subsequent stages there is tumefaction in the epigastrium; vomiting, hiccup, aphthous tongue, bloody stools, and death succeeds from exhaustion."

Acute Simple Dysentery.—Dr. Baly says that mild aperients have been found most useful, perhaps, in the majority of cases, but especially in those where the lower part of the large intestine was the seat of the disease, and where the fæces were retained, so that the evacuations consisted almost entirely of mucus tinged with blood. In these cases the administration of one, two, or three drachms of castor-oil has produced free feculent evacuations, and has afforded great relief to the symptoms. The beneficial effect produced by the action of this mild aperient medicine has often been very remarkable; while evil seems always to result from allowing more than twelve hours to pass without obtaining a free feculent evacuation, if the frequent discharge of bloody mucus and other signs still indicate the persistence of inflammation. In many cases, however, no aperients whatever were required, free discharge of the feculent contents of the bowels taking place spontaneously. Indeed, where the cæcum and ascending colon were the seat of the disease, the active stage of the inflammation was almost always attended with copious discharges of liquid fæces, and the subsidence of the inflammation was in great measure evidenced by the less frequent occurrence of these discharges, and their less liquid character. In some instances, owing to the irritable state of the stomach, small doses of saline purgatives have been substituted for the castor-oil; but whenever they have acted with much violence they have seemed to do harm.

Statistical Results of the Operation for Cataract.—Between the years 1827 and 1844, Professor Jäger (quoted in the "Monthly Journal") operated on 1011 cases of cataract, of which 764 were lenticular, 207 capsulo-lenticular, and 40 capsular. The kinds of operations to which he had recourse were as follows:—

	Cases.
Extraction by the superior section, in....	728
" " by the inferior "	9
Partial extraction	68
Depression	129
Breaking down the lens	87

Of the above number 63 lost their sight; and it will be seen by the subjoined table what were the processes employed which gave the worst results:—

	Cases.
Of the 58 operated on by partial extraction	3
" 738 " " by extraction	33
" 87 " " by breaking down the lens	6
" 129 " " by depression	21

The proportion of those who lost their sight being, in the operation of extraction, $\frac{4}{10}$ per cent.; in depression, 16 per cent.; and in breaking down the lens, 8 per cent.

Separation of the Entire Horny Scalp from Erysipelas.—A man was received into the Hôpital a Charité in April, under M. Velpeau, for a malignant tumour in the parotid region. The operation for the removal of the tumour was performed while the patient was under the influence of ether, and he suffered no pain. For some days after the operation he progressed favourably, but, from some act of imprudence, the side of his face opposite to the wound became affected with erysipelas, which soon extended to the temple and whole scalp, and an abscess formed which covered the entire roof of the cranium; his tongue was dry, the swelling considerable, and the pain severe; he became delirious, yet the pulse remained tranquil, and there appeared to be no fever. Several incisions were made in different parts of the scalp, which gave issue to a large quantity of pus, and the entire of the scalp

was found to be unadherent to the bone; it speedily fell into mortification through its whole extent; it separated at the anterior part, and, by sloughing and contraction, exposed the bone to a great extent, leaving the top of the head one wound. There was only one little spot where exfoliation of the cranium took place; granulations soon covered over the bone, and the enormous ulcer quickly and kindly healed. The restored scalp has now a wrinkled appearance, as if it had been too large, and was plaited in to fit the head. After suffering slightly from diarrhoea and night sweats, he was discharged cured.

Submammary Abscess discharged through the Trachea.—The patient was a female, twenty-nine years of age, attended by Dr. Sewall, of Montreal, for a painful affection of one breast, which was treated by frictions of iodide of potassium ointment, ioduretted solution of iodide of potassium. In three weeks she experienced so much relief as to dispense with further attendance. About three weeks afterwards, some uneasiness remaining, and the breast having increased in size, she was again visited, and upon examination there were discovered indications of matter or other fluid behind the gland. From the depth of the abscess, an incision was not made, and the ioduretted frictions were continued. A fortnight afterwards the patient began to expectorate pus in considerable quantities. Every few minutes a tracheal râle was heard, followed by cough and expectoration of pus. The breast was now the size of the other, and the gland moved loosely under the hand, as though detached. Pressure on the breast caused increased expectoration of matter. A compress and bandage was applied over the breast. The expectoration gradually ceased in four or five days, and the patient has since remained in good health. In this case, adhesion of the pleura, perforation of the intercostal muscle, pleura and substance of the lung, until a large bronchus was reached, must have taken place. There was no effusion of pus into the pleura, or emphysema of the cellular tissue; but there was a loud mucous râle à grosses boules under the axilla.

Treatment of Hooping-Cough.—Dr. J. F. Duncan, in the "Dublin Quarterly," advocates the opinion, that hooping-cough should be classed amongst the exanthemata, and ought to be treated upon principles analogous to those which are found to answer in other members of the same group. The patient should be confined to his room, if not to bed, and put on low diet; gentle aperients and diaphoretics exhibited until the affection has had time to run its course; after which, if the disease do not subside of itself, as it probably would in most cases, the remedies of a tonic and antispasmodic nature, which are found so beneficial in chronic cases, ought to be employed. Of course I speak here only of the simple form of hooping-cough. Instead of this, how common is the practice to allow the patient freely out into the open air, especially if the symptoms begin moderately and the weather is mild, thereby interfering with the proper course of the affection, and running the risk of complicating the case by some of the more dangerous forms of pulmonary inflammation. This habit is unfortunately encouraged by the popular opinion, that nothing is so beneficial to hooping-cough as change of air; which leads some persons from the first, and many others at an early period of the complaint, to resort to this expedient; whereas it is well known to competent practitioners, that, however beneficial change of air may be in protracted cases, the premature adoption of the practice is calculated to retard rather than promote recovery. In the same way false notions have led to similar errors, in reference to diet and regimen during the early stage, that would have been avoided had the opinion here advocated been adopted. Because the child has a good appetite, and is not sick, he is allowed by many persons his usual food; and those evacuations which would have the effect of lowering the fever, and milder the disease both milder and shorter, are generally neglected. Antispasmodics, too, are frequently administered

the cessation of the fever, and, consequently, do more harm than good. Finally, we can understand how it was that so much benefit used formerly to be obtained by stimulating embrocations to the back, the efficacy of which I can readily attest from several instances in which I have used them; but which, I believe, have fallen into general disuse from the abandonment or overthrow of the theories upon which their adoption was recommended. Their utility depended, when judiciously applied, not upon any effect they produced upon the spinal or other nerves, for these were not diseased, but upon the tendency they had to diminish the congestion of the bronchial glands, in the same manner in which similar frictions are used in mumps to reduce the tension and uneasiness of the parotids.

Puerperal Neuritis in the Lower Extremities.—Dr. Simpson directed the attention of the Edinburgh Obstetric Society to this, not unfrequent, but neglected, form of puerperal disease. He had seen several cases mistaken for phlebitis and other forms of phlegmasia dolens. It was characterized often by numbness and tingling of the affected limb; and pain, fixed or remittent, passing along the crural or sciatic nerve down to the knee, calf, or even the foot, increased by pressure along the course of the nerve, and by stretching of the limb, sometimes relieved by strong pressure on the highest portion of the nerves. Sometimes there was no coexistent oedema, or if it were present the pain was in a degree greatly disproportionate to the oedema. It was often very protracted in its course. After local leeching, an elevated position of the limb, the application of belladonna, aconite, &c., greatly relieved the patients.

Puerperal Convulsions connected with Inflammation of the Kidney.—Dr. Simpson pointed out the connection of puerperal convulsions with derangement of the kidney as a very striking fact in obstetric pathology. He had seen *post-mortem* appearances of nephritis in some fatal cases of convulsions. In one case, the patient, a delicate female, was exhausted by the pains of labour, and complaining of severe headache, when convulsions supervened. The child, which was dead, was promptly delivered by turning. The convulsions gradually subsided, but reappeared several times. In the intervals she was comatose, and died forty hours after the first attack. Upon a *post-mortem* examination, when the lateral ventricle was opened, fluid blood escaped. The corpus striatum, and outer part of the optic thalamus, were broken up and mixed with a large quantity of coagulated blood, forming a considerable clot. The fluid blood was found in the opposite lateral, and also in the third and fourth ventricles. The right kidney was converted into numerous cysts of the size of a walnut, containing unhealthy pus, which passed along the ureter, and filled the bladder. The left kidney exhibited an advanced stage of Bright's disease. In another case, in which the labour was natural, and recovery appeared perfect, the patient, seven weeks afterwards, was seized with the most severe convulsions, which proved fatal in three hours, the patient during that time never being perfectly sensible. The pelvis of each kidney was found filled with a whitish-purulent matter, and its mucous lining membrane coated with large patches of adherent coagulable lymph. The ventricles of the brain were filled with serous fluid. No sign of albumen in the urine. In a third case, a convulsive fit came on a month before delivery, and recurred in a severe and fatal form a fortnight after delivery. The urine had presented no traces of albumen. At the autopsy, some whitish turbid fluid was found in the renal pelvis, and could be pressed out abundantly from the renal papillae. Under the microscope it seemed to contain merely a very large quantity of epithelial cells, and no pus globules.

Calculus from the Stomach of a Llama.—Dr. Schlossberger, professor of chemistry in Tübingen, received from Professor Von Rapp a concretion the size of a horse-bean, which he had removed from one of the numerous cells in the first stomach of the llama; it had a greenish-

brown colour, and yielded to ether, when boiled in it, a green pigment, apparently identical with chlorophyll. On being broken in pieces it was found to consist of a grain of corn as a nucleus, coated with numerous thin and differently-coloured layers of earthy salts, manifestly precipitated from the fluids of the stomach and those of the nutritious matters contained in it, upon this organic nucleus thus imprisoned within one of its cells. Undoubtedly this precipitation took place in the cell, which was, consequently, considerably dilated; the opening into it being, however, much too small to admit of the entrance of the calculus, and scarcely large enough for that of the barley-corn, an incision had to be made into the opening of the cell to extract the calculus. The lamellae of this concretion consisted, in 100 parts, of

46.61 phosphatic earths, with traces of earthy carbonates and chloride of sodium.

14.59 organic matters.

38.80 water.

Auscultation in Labours.—Dr. McClintock, in "The Dublin Quarterly," gives the following aphorisms, as embodying the truths which he has ascertained in reference to auscultation in labours:—1. When the fetus is alive, the sounds of its heart may be always detected at some period of the labour.—2. The precise region of the abdomen in which the fetal heart is heard affords auxiliary evidence of the position of the child *in utero*, but can never be relied on alone for determining this point, or supersede the necessity for vaginal examination.—3. In presentations of the lower extremities, whether it be breech, foot, or knee, the fetal heart is usually heard most distinctly in the vicinity of the umbilicus of the mother.—4. Conclusively auricular evidence of the existence of twins *in utero* is only to be drawn from the inequality of the number of the beats of the new fetal hearts, and not merely from any difference as to their respective positions.—5. If, in the course of a tedious or difficult labour, the fetal cardiac sounds, from having been distinct and clear, gradually become feeble and obscure, and ultimately inaudible, even with every precaution against deception, their absence is positive evidence of the child's death; but without the previous successive examinations this conclusion would be destitute of any positive character.—6. In cases where ergot of rye has been given to hasten delivery, auscultation is the only certain way of discovering when the medicine is beginning to exert an injurious influence on the child. 7. In cases simulating rupture of the uterus, the persistence of the fetal heart's sound is a strong proof against the occurrence of the accident, and the more advanced the period at which they are audible after the setting in of bad symptoms, the more conclusive is the evidence that rupture has not taken place; whilst the sudden cessation of the fetal pulsations, where they had been distinctly audible a short time previously, would corroborate strongly other existing symptoms of laceration of the uterus.—8. After an attack of puerperal convulsions in the seventh or eighth month of pregnancy, when labour has not immediately supervened, if the stethoscope shows that the child is alive there is hope that gestation will go on undisturbed; but, if the child be dead, its expulsion will take place most probably in ten or fourteen days from the date of the convulsive attack.—9. No certain conclusion regarding the state of the fetus can be drawn from the placental souffle.—10. In cases of flooding before delivery, the placental bruit may point out the part of the uterus to which the after-birth is attached, and thereby show whether the hemorrhage be accidental or unavoidable.—11. Auscultation of the heart in stillborn children more accurately acquaints us with the state of the child's vital powers, than any other source of information, and is, therefore, well deserving of employment in all such cases.

Mr. J. Marshall has been appointed to the office of Demonstrator at University College, in the room of Mr. Philip Potter, deceased.

RUPTURE OF THE BLADDER.

By ABM. C. SWAYNE, M.R.C.S.E., Carriick.

Patrick Gormly, a labouring man living near this town, had been carting some stones, and when unloading, with the aid of another man, the back shaft struck him rather forcibly in the lower part of the abdomen. He immediately fell down in a syncope, from which he gradually recovered, and then complained of severe pain in the stricken part. He soon after fainted again, in which state he was conveyed home and placed in bed.

At two o'clock P.M., on the following day, I was sent for (eighteen hours after the accident occurred); and, having learned the foregoing particulars, I proceeded to make the necessary examination. I found the hypogastric region exceedingly tense and swollen; the pulse quick, sharp, and wiry; intense thirst; and a tormenting but ineffectual desire to pass water, as evidenced by the constant straining, accompanied with pains shooting down the thighs, somewhat simulating the bearing-down pains of labour. I bled him largely, and, having introduced the catheter, drew off about three pints and a half of high-coloured urine, partaking somewhat of a sanguinolent character. This relieved him of the distressing attempts he made to empty his bladder. The pain, however, in the abdomen still continued up to the time I left him, after having promised perfect quietness, and the application of a dozen leeches over the part, together with a calomel-and-opium pill every two hours. On my next visit (the following morning), I found the whole region of the abdomen greatly swollen, with a very perceptible fullness over the hypogastrium, on placing my hand over which, the poor fellow moaned piteously. His pulse was 140, and very feeble; no urine came away since the employment of the catheter on the previous day; a second introduction brought away about three pints of a very high colour. A few more leeches were now applied; but, notwithstanding all the means tried, he rapidly grew worse, and expired at eight o'clock the same evening.

Post-mortem Appearances.—Upon opening the cavity of the abdomen, the intestines were covered with plastic lymph, and glued together; the bladder lay collapsed, and a large transverse rent was seen at its superior fundus. The urine, escaping from this viscus through the rupture, had accumulated in a cavity immediately above the bladder, formed by the adhesions which tied the small intestines together, and the fluid was thus permitted to accumulate without becoming diffused through the general cavity of the abdomen.

Remarks.—The circumstance last mentioned explains the facility with which the urine had been drawn off by the catheter, inasmuch as the extremity of this instrument could without difficulty pass through the rupture in the opposite fundus into this part of the peritoneum, bounded thus by adhesions. On close examination of the rent, I found it of much greater dimensions through the peritoneal coat than through the muscular and mucous, which would be, I presume, accounted for by the more contractile nature of the latter tissues. I have not heard or read of an instance where rupture of the bladder occurs in any part, save the superior fundus; and I think the best explanation of the fact is that given by Professor Harrison, of Dublin, who accounts for its invariably occurring in that particular part of the viscus by the circumstance of the bladder being always in a distended state when this serious accident occurs; and, rising above the pubis into the hypogastrium, it is subject to be compressed against the sacro-lumbar eminence of the spine, thus throwing the chief pressure of the urine towards the superior fundus. It was quite evident, from the nature of the accident in the present case, that such must have been the cause; and also, from the great extent of the rupture, that the chance of the life of the individual being saved was utterly hopeless.

TO CORRESPONDENTS.

THE MEDICAL TIMES may be procured by an order on any *newspaper or bookseller*, or it will be sent direct by post from the Office of the Medical Times to Subscribers sending by a Post-office order, directed *James Angerslain Carfrae*, or on order on some party in town, One Guinea IN ADVANCE, which will free them for twelve months. Half-yearly Subscription, 13s.; Quarterly, 6s. 6d.

Mr. C. Heslop is thanked for his interesting communication; it shall receive that early attention which its importance demands.

An Old Sailor.—The case is one which requires immediate attention, and some respectable medical practitioner should be consulted. We would advise our correspondent not to quick himself, and to keep clear of all advertising harpies.

S. D.—It is not an uncommon thing, nor is it derogatory by intelligent individuals, or is it to perform surgical operations, even when with public institutions. Medicine and Surgery are one and indivisible, and he who disciplines his mind by the most extensive study is the most likely to prove the most successful practitioner.

An Old Subscriber.—Physicians, members of the College of Surgeons, and licentiates of the Apothecaries' Society, in actual practice, are exempt from all parochial officers, and from serving on juries.

Candidatus.—The Army Medical Board should be memorialized; it is possible, and very probable, that a name may be placed on the list, and a length of time elapse before an appointment is obtained.

Chirurgus.—From the few facts stated we are unable to give our opinion as regards the propriety of an operation. In a case which is represented to be so critical it would be well to have the opinion of some neighbouring practitioners.

Delta.—Ung. hyd. fort., or hyd. protochlorid., will effectually destroy the pediculi. One application is often sufficient.

Caustic.—We do not insert anonymous attacks upon character. Our correspondent evidently possesses talent, which might be usefully employed on scientific subjects.

A Reformer.—By addressing the secretary of the National Institute, Mr. Ross, 4, Hanover-square the desired information may be obtained. The Institute is prospering, though so many attempt have been made to effect its ruin.

A Union Surgeon.—We know of no better plan to bring the guardians to their senses, if they have any, than by giving publicity to their conduct. We have a large mass of correspondence which relates to the doings of these worthies in different parts of the Kingdom.

Dr. L. Tinson.—The parties engaged in publishing the work are bound to fulfil their promises. If our correspondent will send us a communication on the subject adapted for publication it shall appear in our columns.

A Druggist.—A person not duly qualified, who visits and prescribes for patients, with a view to profit, is liable to a prosecution under the Apothecaries' Act.

A Pupil of St. George's Hospital.—"Cooper's Surgical Dictionary."

S. G., Dublin.—The paper received on Fracture of the Base of the Skull is not complete; the concluding part is missing, which has caused the delay. It was by an oversight that no mention was made of it last week in the Notices to Correspondents.

A Medical Practitioner, Norwich.—Mr. Startin was the first to recommend glycyrrhine in certain skin diseases. It is a peculiar uncrystallizable saccharine matter, found in animal fats and oils, or produced during their admixture with alkalis and acids. It is very abundant in the refuse of the soapmaker.

A Navy Surgeon, Portsmouth.—We have not lost sight of the subject, and if our correspondent will furnish us with the facts to which he adverts, they shall receive all due attention.

Athlous, Liverpool.—The Government has determined that the act in reference to passenger

vessels shall be enforced. There has been too neglect in times past.

Mr. Morris.—Mr. Daniell, of Newport-Pagnell, will furnish the desired information.

M. D. (A Subscriber).—The Manual of Dr. Guy.

An Inquirer.—Healthy urine contains no albumen: in chronic albuminuria it varies in different cases, and in the same case at different periods of the disease.

M. F., Guy's Hospital.—The pay of an assistant-surgeon in the army of less than ten years actual service is 7s. 6d. a day.

A Lover of Truth, Bristol.—A good microscope will cost a considerable sum; such an instrument is requisite, especially to one who is a novice in the science.

A Graduate (Edinburgh University).—Foreign medical men can still practise in France under certain regulations.

A Non-Medical Subscriber, Kingsland.—The Editor of the Pharmaceutical Times will, on application, give our correspondent all desirable information in reference to the best powder for cleansing and preserving the teeth.

Mr. E. Whitehead, Dakinfield.—Communication received, and shall have an early insertion.

Electron.—Noad's Lectures.

Paralyticus.—The parties to whom our correspondent refers are rank quacks, as their advertisements, forwarded to us, prove.

Filius Agricole will find his questions answered elsewhere.

In the letter upon "Coroners and Medical Witnesses," inserted last week, the signature should not have been Wm. Mayling, but Wm. A. Maybury, 8, Little Tower-street.

Letters and communications have been received from Dr. P. S. Waddy; Dr. Grattan; A Medical Practitioner; A Navy Surgeon, Portsmouth; Amicus, Liverpool; Mr. Morris; M.D., a Subscriber; An Inquirer; M. F., Guy's Hospital; A Lover of Truth, Bristol; A Graduate, Edinburgh University; A Non-Medical Subscriber, Kingsland; Mr. E. Whitehead, Dakinfield; Mr. W. A. Maybury, 3, Little Tower-street; Electron; Paralyticus; S. G., Dublin; A Pupil of St. George's Hospital; A Druggist; Dr. L. Tinson; A Union Surgeon; A Reformer; Caustic; Delta; Chirurgus; Candidatus; An Old Subscriber; S. D.; An Old Sailor; Mr. C. Heslop; Mr. Shaw, Ashby-de-la-Zouch; Mr. Thetford, Clones; Dr. Allinson, Bridlington; Mr. Chapman, Uttoxeter; Dr. Palmer, Durlanagh; Mr. Nelson, Isle of Man; Mr. Bridges, St. Albans; Mr. Tby, Hartford-bridge; Dr. Atkinson, Castlebar; Mr. Cowdry, Great Torrington.

Messrs. Wright, Fletcher, and I'anson, the gentlemen gaining the Medical Times Prizes, are informed that the certificates are now ready for them, and may be obtained at the office.

THE MEDICAL TIMES.

SATURDAY, SEPTEMBER 11, 1847.

GENERAL CONFERENCE OF POOR-LAW DOCTORS.

We do not know a better moment than the present for a smart agitation of the question of Poor-law Medical Relief. There is a lull of home politics that solicits the grievance into notoriety, and invites it into the noonday of public observation and discussion. We should confer a favour on the dull public by giving it so tough a hardship to grumble at. That great lever of social reform, the Times, has shown not a few anxieties to do battle on the subject, and is ready to take the field any day that we supply that generalissimo of public opinion with a fair army of facts and figures to fight with. Besides, the nuisance is itself growing intolerable, and is

perking more every day its offensive odour under honest men's noses. The papers teem with records of its baleful influence. We have only, then, to come out strongly, in unison, and with firmness, to create that public impression which alone can—as it one day will—remedy the abuse.

It is an established fact that the union doctors do not receive for their labours one-half as much as they would be entitled to if their services were estimated as those of any journeymen mechanic. They are scarcely paid their expenses out of pocket. Here, then, without circumlocution or fine-drawing, lies the root of the whole evil. Thousands of hardworking gentlemen are robbed of their fair wages, and the well-being of the poor in the prime article of health is made to depend on the virtuous, the honest, and self-denying services of defrauded and plundered servants. Everything is made by the State, too, to depend on the fact that the servants are far more honest than those who pay them.

Are the medical men, then, true to their discouraging charge? Do they conscientiously hand over to the State that medicine and those attentions for which they shall never receive payment? Many are thus true and conscientious, and pay the penalty of their probity in a yearly loss of income. We are proud to think that the general rule is virtue under these most trying circumstances; but we must add that our regret is the greater that a State can be found to persecute and injure such deserving subjects, and offer in their persons, when hurried by probity into the workhouse, a public warning to others of the calamitous end that awaits in medicine a conscientious discharge of an honourable public trust.

Follow into the details of private life the union doctor, who thus sacrifices himself to his unwisely assumed responsibility, and we catch a better view of the atrocious wrong of which he is made the victim. Unpaid by anybody, he is everybody's servant. He has masters in dozens of poor-law commissioners—in scores of guardians—in union clerks—relieving officers—and, finally, in the paupers. He can count on no hour of domestic ease uninterrupted—no day of repose undisturbed. By night, by day—in foul weather or in fine—winter, as in summer, his person is always under orders for almost all distances; and, after years thus painfully given to services that know neither of reward nor promotion, he dies, not improbably of fever caught in the discharge of an unremunerated duty, and leaves a wife with children wholly unprovided for. This is neither a rarity nor a romance. Within the last month one district—that of Great Bolton—gives us two such cases! Mr. Richard Robinson perished in this way a few weeks ago; and only a few days since was followed by Mr. Henry Hutton, the medical officer of the same district!

But if many are thus honest and self-sacrificing even unto death—it is not what the State has any reason or any justice in counting on. We know enough of human nature to be assured that there are exceptions—not unfrequent—men who, applying to their medical performances the same rule as butchers and bakers to their commodities, will give nothing for nothing. The State pays them but for bad drugs and poor attendance; and bad drugs and poor attendance is all they will give the State in return. There must be no misunderstanding about this matter. There

are some men who will not victimise themselves for a parsimonious union, and the result is that the paupers suffer. This low—this infamously low—system of payment coolly and deliberately contemplates and sanctions one of two results—the robbery of the honest medical man, or, in a modified form, the assassination of the pauper!

It is right that these facts should be kept incessantly under the public eye, and it is with great complacency we notice in the *Times* of this day (Thursday) an able letter from its clerical correspondent, S. G. O., securing general censure to the principle on which these extraordinary injustices are perpetrated. The following extract will be welcomed as a friend by many a union doctor:—

"Union doctors are not paid in proportion to what is expected of them so well as veterinary surgeons; they could not live except by the addition of what they get from private patients in their rounds. We expect the farrier to do his utmost for our horses or cows because he is paid for what he does, or professes to do; it is folly to expect the union surgeon to give all the attention and appliances to a pauper that he must feel the said pauper ought to have, because we know his salary scarce finds him in the expenses of his journeys. We don't in reality profess to pay him for what he is to do for the pauper. If he don't take what we offer, we know some young or some bankrupt practitioner will bid against him, on the principle of getting on the ground anyhow, in hopes that he may pick up at last a living out of private patients. Thus, from one end of the country to another, are the interests of the poor, when pauperized, dealt with. It is a principle not merely applicable to lunatic asylums and union M.D.'s; again and again do we hear of the neglect of relieving officers and other paid officials. But, sir, how are these men selected? Let a board have a humane and active chairman, for nine weeks out of ten the whole burden of the business, with all its odious detail, is thrown on him, and, perhaps, one or two other guardians, who think it right to attend to help him. A relieving-officer dies, resigns, or is dismissed; at once there is a stir in the market; whom shall the great *we* elect becomes the question: for in the rural districts the magnates of the market are the great dispensers of union patronage. 'Us' and them' mean the tenantry and their landlords; if the latter will support them, all very well; if not, 'us' won't be beat. A place of trust, requiring a man of undoubted respectability to give his whole time to it, is open—the salary, perhaps, from £70 to £90 a year; 'us' looks about us; some jolly good fellow who may have failed in business, or be next to a pauper because he never would attend to anything, is immediately singled out as the favoured object of market favour; 'us' determines to return him against all opposition; at the appointed day the chairman finds the board-room crammed to suffocation; in vain are testimonials of ability and respectability produced by other candidates, the pet of the market receives a support that bears down all opposition, he receives only one piece of advice from his backers—i. e., 'to keep the rates down;' and thus, again and again, has it and will it happen, that all regard for the poor themselves, all respect to those who take the labouring oar of the union, are shelved, that the great 'us' may show their importance, their sense of the value of these offices as refuges for the destitute of their friends."

Now, it is time that we tell the guardians, in a fashion not to be contemned, that we are no longer to be either victims ourselves or agents in the victimisation of others—just "to keep down the rates." How, then, is the change to be effected? By an IMMEDIATE CONFERENCE IN LONDON OF UNION DOCTORS. Let a correspondence be immediately commenced: let arrangements be forthwith settled for a meeting: let every union doctor be invited: let a permanent organization be agreed

on: and in less than twelve months we must have a thorough reformation. The power is in the hands of the union doctors themselves: and the profession and its press will not fail to support them. We shall take care that there shall be no more recurrence to the "bidding system" and invitation of "bankrupt practitioners." The organization may and ought to include every legally-qualified medical man, for it concerns equally the interests of all; and he would be a bold man who, in the face of such a combination, would aspire to the bad eminence of accepting an ungentlemanly employment in the service of an assassinating parsimony.

There should be no delay: now is the opportune moment: let the most worthy at once show himself by acting as secretary to the movement: *c'est le premier pas qui coûte*. Once commenced, the success of the movement must be complete.

THE DUC DE PRASLIN.

SINCE penning our last article on the most remarkable event Paris has witnessed since 1830, additional facts have been published which, while modifying some of our opinions, only confirm the censures we felt compelled to express on the conduct of Louis, Andral, and Orfila.

If it be granted—as some apologists insist—that the criminal took poison but once, and that on the very day of his crime, the duke's case must have been more than ordinarily amenable to judicious treatment. It is not in the attributes of arsenic to take six days to accomplish its fatal purpose. Twenty hours is more than its average requirement; and we may lay it down as a toxicological maxim that, when the patient survives six days, he dies at last by other agencies than the arsenic. The agencies here were a mistaken diagnosis, and worse treatment.

The celebrated, and on many accounts justly celebrated, Louis is called in the day after the poisoning. His patient is a prisoner: the charge is murder: the evidence overwhelming. Before him lie every symptom that indicates poison: anxious countenance, sunken eye, extreme prostration, universal sense of cold, continual vomiting of green matter, frequent dejections, scarcely any pulse. M. Louis, however, will see nothing but cholera in all this; and, in combating that hypothetical enemy, gives the arsenic every aid to diffuse itself through and overpower the whole system—warm baths, abundant cold drinks, warm towels to the stomach, bleeding, &c. The distinguished Andral singularly enough coincides in the justness of this treatment, which has the further sanction of two other French physicians, Drs. Reymond and Rouget.

Despite, however, all these aiding agencies, the patient rallies on the third day—but the arsenic having been placed in full power, and the efforts of nature to dislodge it, or sustain itself, too successfully resisted—he grows worse the next day, and, exhibiting the usual succession of arsenical symptoms, dies on the sixth day.

The mistaken diagnosis, although it accounts for, does not excuse this maltreatment: but what shall we say of the course taken when the existence of arsenic had become ascertained? In what way was nitre and camphor—other poisons—to soothe the intestinal burning or neutralize the arsenic? Of what avail could be the warm bath? And still more, in what way could twenty-four leeches strengthen and uphold the organism, under the direful conflict it was sustaining?

The fact is, indeed, too clear—that some of the

most celebrated physicians of Paris cannot recognise a clear case of poisoning, when there is every circumstance present to indicate its existence; and when they are at last made to recognise it, do not then know how to treat it. All this behaviour to the Duke of Praslin was of a kind to make fatal a dose of arsenic, not fatal of itself.

Orfila—we see—accounts for the extraordinary length of time the arsenic took in completing its task, by supposing, first, that the duke took laudanum (which appears now not to be the fact); and secondly, that this laudanum, paralyzing the mucous membrane of the stomach, made absorption slow. Such a paralysis being not only new to science, but impossible, in fact, we must decline to accept his high authority, which, let us say, *en passant*, we regret to see compromised by a dynastic partisanship as suspicious as it is ill placed.

CORONERS AND MEDICAL WITNESSES.

THE "coronership" is a tumbledown office that seems kept up on no better principle than that which preserves for us that obstruction of metropolitan commerce—Temple-bar. If worse than useless, it is old; if costly, queer; and an ancient reminiscence, especially if a little *blasé*, is entitled with some to large sacrifices of present convenience. People won't see that in a thousand ways we have outlived the coroner and his antiquated habitudes, and that they are not less out of place in the nineteenth century than would be the ruins of Netley Abbey in Birmingham market-place. The machinery of the thing has worn out and disappeared. It has been silently superseded. Its business of crime-detection has fallen or risen into other hands, and the thing is now but a ceremonial, lifeless as the corpse it sits over. Modern legislation knows nothing of the coroner. He is without court, tipstaff, or erier. Statutes know him not, except in the boon of "deputyship" (contemptuously thrown to a grumbler a session or two since). Parliament resolutely persists in looking to the police and their magistrates for "limb and life." Coronership has become, in fact, as obsolete as its kin-Dogberryship, though longer lived. Its importance is just as mock.

Yet this ghost of a tribunal—this traditional fiction of a legal jurisdiction—can manage now and then to show some little vitality in troubling the rests of sundry medical practitioners. If ever we hear of the spectre it is as haunting and persecuting some unfortunate doctor. The law seems to let it walk the earth still—every other purpose wanting—for our especial malediction. Even Coroner Payne, who enters so fully into the nonsensicalness of his office, that to joke a colleague he will sit on a case of arsenic—like a matronly hen on a cockatrice's egg—can be quite serious in harassing a medical witness.

Mr. Maybury (as his letter to us last week shows) was punctual in obeying his summons: and was just as punctually deprived of his allotted guinea. As an acknowledgment of his legal obedience he was left minus his time, trouble, and golden guinea. Such are the punishments of a medical witness's punctuality, even in the comparatively respectable court of Mr. Payne! Coroners' annals are full of these cases of painless and painful extractions.

Our office is visited in this way, on an average, three days a week with some medical complaint of coroner-hardship. "Is the coroner allowed to do this?" says one. "Has he power to do that?"

says a second; and so on ask, perhaps, a third and a fourth. In nine cases out of ten, governed by our *good nature* (a usual thing with us), we answer by a solemn "no;" adding our protest to that of "An Injured Subscriber," "An Indignant Constant Reader," and "One who has no more Patience with a Medical or Non-medical Coroner." Now, this has been all very good-natured in us—but—and we will make a clean breast of it—it is not *all* the truth. We ought to have said also—that, though the coroners *can't* do the things they dally do, they would be made of very different stuff to any that now forms their worshipful persons if, with the present acquiescence and tameness of the medical body, they condescended to act in another fashion.

Of the thousand injustices that coroners have inflicted on medical men for the last ten years, which one of them has been brought under judicial cognizance and censure? Not one! Yet how many the sufferers? How loud the grumblers? Not one!

But we mistake: we forget naturally enough one case. We *did* bring one startling case under Lord Denman. We obtained one of the most remarkable decisions in legal history; and this too—to make it all the more remarkable—in *favour* of medical men.

1. Coroners were in the habit of taking round with them a pet surgeon who got all inquest cases—*post-mortem* fees on one side and newspaper mention and laudation on the other. Lord Denman laid it down for us that this was illegal, and that such coroners might be indicted for a misdemeanour.

2. Coroners were in the habit of dispensing with the medical witness who attended the case before death. Lord Denman laid it down for us that this was illegal, and that such coroners might be indicted for misdemeanour.

3. Coroners were in the habit, on slight pretences, of treating medical men—who attended cases before death—as parties accused, whose statements should be submitted to juries without the sanction of an oath. Lord Denman declared this usage illegal and punishable.

Now this was not a very commonplace vindication for medical men. Passing by that, it cost a fair sum of money (with the risk of more), liberty as well as purse hanging on the question—a tolerably-sized privilege was laid hold of, and a rather useful example established. Well, what has been the result? Coroner injustices lessened? Very little. The law, though ascertained, is left unused. Medical grumblings fewer? Not at all. Any throwing themselves in the breach, and giving effect to Lord Denman's decision? Not one! Not one effort has been since made to keep the ground then taken. The boon with everybody was inestimable, but nobody has done anything to retain it. There has been no meeting—no association. To the old aggressions repeated, as to the new since invented, we have but the old answer—feeble and isolated complaints through the *Medical Times*.

As of individuals, improvement is hopeless where gratitude is extinct, so of communities, all is gone where public spirit is fled. There is no salvation where every one cries help, and nobody gives it. Our columns are becoming the Lamentations of the Jeremiah of British Professions; and, as if to augment superabundance and add to excess, we, too, come in *lamenting* also—what? That we are the hearers of so many groans and the witnesses of so few actions! It really is time that in this walk of grievances, as, indeed, in many others,

we should *work*. Where not in combination, let it be done individually. Let us for once be refreshed by the sight of some town or village Hampden refusing in *his own person* to submit to injustice, and, by the indictment of some misdemeanant coroner, showing the world that Lord Denman's judgment is not to remain a dead letter.

As for Mr. Maybury, who has been deprived of a guinea as much his *property* as the inquest fees are the dues of the recusant coroner, let him summon Mr. Payne before a County Court, or Court of Requests, and *enforce* the payment the law *ordains*. The example will do good, and its expense is not costly. We only advise what we have ourselves done on a somewhat larger scale.

MEDICAL ATTENDANTS OF PRISONS, AND CHAPLAINS.

THE subject of medical fees has of late been so extensively discussed that there is danger of our being viewed by the public as a money-loving profession. This particular agitation, however, has been commenced and carried on, not that an avaricious spirit should be gratified by increased pay for services performed, but that the cause of humanity and professional respectability may be maintained. A medical fee is not so much a *quid pro quo* for work done as a testimony of respect to the person who receives it. The salaries which are obtained, therefore, by medical officers holding public appointments, not charitable, may be taken as a good criterion of the estimation in which they are held by persons in authority. If this be true, we are compelled to acknowledge that the members of our profession do not occupy that high position to which their talents and calling entitle them.

Of the three professions which, by universal consent, are acknowledged learned, the medical is the hardest worked and the worst paid. The lawyer and divine receive for their services something like respectable remuneration, while there are valuable sinecures in reversion for many of them in the season of declining life. It is not so with us: for a life of usefulness is too often embittered by straitened circumstances, and terminated without realizing the blessings connected with a state of affluence. We can by no means admit that the vocation of the divine is so vastly superior to that of the physician as we may be led to suppose from the different remuneration they receive for their services. It is true that the one has to do with the spiritual, the other with the material, part of the man; the one proffers future blessings, the other brings with him blessings for the body, to be enjoyed now, in this time and state, where flesh and blood are such important ingredients. Moreover, the healthy exercise of the attributes of the mind are closely connected with the healthy action of the organs of the body, and in many instances the functions of the priesthood would be exercised in vain were it not for the skilful appliances of the healing art to suffering humanity. And yet we find that, where the two obtain public appointments in the same institution, the former receives not unfrequently a salary treble in amount to that of the latter.

The chaplains of prisons and workhouses have not to undergo a tithe of the mental and physical labour which falls to the lot of medical officers, and yet how much better are they paid! In the newly-enlarged prison, at Wakefield, arrangements have been made for the occupation of 400

additional cells, and the Government plates sending thither a number of prisoners from the Millbank Penitentiary, under sentence of transportation. These convicts are to have a separate chaplain, surgeon, and wardens; the former at a salary of £250 a year, the latter at salaries varying from £90 to £80 and £60 per annum.

Now, what we complain of is this, the invidious distinction which is made between the clergyman and the doctor. Why the one should receive so much more pay for his services than the other we are unable to conjecture, as sound health and good morals are closely allied. We cavil not at the amount which he who has the cure of souls receives further than the relation it bears to that which he who has the cure of bodies obtains. The one has a salary befitting a scholar and a gentleman, the other that of a turnkey or any other menial. The Government has here manifested the same spirit in rewarding medical men who are attendants of prisons as it does to those who are officers of poor-law unions.

These facts palpably show that the members of the medical profession of Great Britain have not yet attained their legitimate position in society, while they should also be taught the important duties they owe to themselves. The first blow for their emancipation must be struck by their own hands, and in the right place; the set time to favour them is come, and it is for them not to allow it to pass away neglected or unimproved.

SUGGESTIONS ON POOR-LAW MEDICAL RELIEF.

[To the Editor of the Medical Times.]

SIR,—There are few who will be disposed to deny in the abstract that human life is a gift so valuable that no expense is too great to be incurred in order to promote the healthful discharge of its functions, or to preserve it from the manifold dangers to which it is exposed. The principle of self-preservation is powerfully felt by all, so much so, indeed, that no sacrifice would be considered too great to purchase an exemption from the attacks of disease and death. The position which an individual occupies in the scale of society neither increases nor diminishes the value of life: for, while it may affect the external relations of a man, it adds nothing to the original attributes of his intellectual existence. This great fact is recognised in the laws which regulate society, the same punishment being awarded to one that is rich and noble for taking away the life of a pauper as to another who, without worldly distinctions, commits the same offence against a favourite of fortune.

As there are no degrees in the value of human existence, so that there are none in the obligations to preserve it; and while we owe to ourselves the use of all the means which Providence has placed within our power for self-preservation, we are equally bound to employ them on behalf of our fellow-creatures, when from any cause their resources are less than ours to promote their well-being. Natural benevolence prompts us to rush to the help of a drowning man, or one placed in danger equally palpable and imminent, and where this common attribute of humanity is violated society resents the insult by a moral punishment when her laws are inadequate in any other way to meet the case. Moved by the same principle, she has established for the helpless poor asylums where ostensibly their

poverty may find relief, and their sufferings mitigation. The laws for the relief of paupers were originally prompted by a spirit of benevolence, and, if they had been administered under the influence of the same spirit, the public burdens would not have been increased, while a vast amount of suffering would have been prevented. It would, perhaps, be thought that I travelled out of the path of duty were I to occupy your pages in denouncing the injustice as well as the impolicy of keeping down paupers to the starving point by a reprehensible parsimony: unjust it is, because adequate funds are provided, when they are applied to their legitimate purposes, for their relief; and impolitic it is, because it unnecessarily exposes them to the invasion of disease, which in numerous instances makes the sufferers become burdensome to the public throughout their subsequent earthly existence. What I have now more immediately to do with is the injury which is inflicted on sick paupers by the illiberality which is manifested towards their medical attendants. The public has no right to expect that duties will be efficiently performed where service is not adequately remunerated, for it is expecting too much of any man that he should as cheerfully and as usefully discharge the functions of his calling where the reward bears no proportion to the labour as in cases where it does. If the proposition which I have stated at the commencement of this letter be correct, then are the lives of paupers quite as valuable as the lives of "guardians;" and these, in refusing to pay their medical officer a just sum for the exercise of his professional talents, do not employ all the means in their power to promote the well-being of those who are especially committed to their care.

You published last week a letter from a gentleman, "A Poor Union Surgeon," which serves to illustrate the left-handed justice which guardians administer to their medical servants and their pauper dependants. Your correspondent exercises a degree of charity towards the parochial executive to which it is not entitled in my estimation, and would place all the blame on the law and the commissioners. We are told by your correspondent, that his district "contains eight parishes; an acreage amounting to 14,000; a population of 8000, three-fourths of which are on the verge of pauperism from the long-continued depression in trade. In the course of the year he has to attend upon an average 800 patients, to ride nearly 3000 miles, and to be ready, night and day, to visit a distressed sick population. For these duties he receives the liberal sum of £50 per annum; for which he has also to find medicine, leeches, and all other appliances necessary in sickness. Is it to be expected with such pay that the surgeon could do justice to his patients, if he would? If he does, I can only say, he must be very unjust to himself and horse. Of course his work is not always done in the day, neither has he always a fair sky nor good roads; a horse turned out at all times and in all weathers, and going over 3000 miles of ground in the course of a year, must, in spite of bottom and courage, soon become so "groggy" as to require his place to be occupied by another, if the master has any regard for his own neck. For such work one horse must be kept entirely for the service of the poor, which cannot be done, as your correspondent states, for less than £20 a year, and £5 for wear and tear. Here is half the salary at once gone; and add to this the sum

of £30 for medicine, leeches, &c., the surgeon gains by his appointment a clear loss of £5! Were it a question of mere profit and loss to him, it might be quickly disposed of, because parishes would have an undoubted right to choose a professional person who would undertake to do the most work for the least money. It is not, however, a matter which has simply to do with pounds, shillings, and pence, but one which involves the temporal welfare of a large number of our suffering fellow-creatures. It is upon this high ground the profession must take its stand, while it demands for its members such a just reward for the services they render to the sick poor as shall secure for them a cheerful and efficient attendance in the hour of need.

The evils of which all now complain have been fostered and strengthened by causes which have been long in operation, and one of the most powerful is the peculiar constitution of the medical community in our country. A variety of qualifications has produced numerous divisions, and persons in authority have used these to depreciate the value of medical services. In other callings, not professional, individuals unite for mutual protection and support, but it seems to be our unhappy lot to belong to a house divided against itself. The question of medical remuneration I conceive, therefore, is closely connected with that of medical reform—such a reform as shall gather into one body the general practitioners, consolidate their energies, and heal the breaches which have so long existed amongst them. Humanity will rejoice at this, because, while it will elevate the character of the profession, it will increase its usefulness also.

It is a mistake to suppose that the medical officers of poor-law unions will be able to obtain from the Government or Parliament a recognition of their claims by solely forming an association amongst themselves; their brethren must be co-workers with them, or nothing will be accomplished. A universal organization is what is required, whose efforts shall be directed to promote the general welfare of the profession, and, this being accomplished, must inevitably be productive of good to the public. At the same time I think my brother union officers cannot too soon meet in some central point, and lay down the basis of some future combined operations. Let them once put their heads together, and take my word for it their position will be improved by the effort.

VINDICATOR.

MEDUSÆ, AS IRRITANTS TO THE SKIN.

[To the Editor of the Medical Times.]

SIR,—My attention has been called this summer to a fact which seems new to the naturalists and medical practitioners in this vicinity. It is the circumstance of the medusæ, or, as they are called here, *lock-livers*, acting as powerful irritants when applied to the skin. These animals, of which there seems to be a great variety, float in vast numbers at this season of the year along the coast, and are frequently left on the beach by the ebbing of the tide.

A girl, lately happening to trample on one of them with her bare feet, instantly complained of acute burning pain in them, and in a few minutes the skin assumed a bright red appearance similar to that produced by the application of a mustard poultice. By means of olive-oil, and the parts being enveloped with cotton wadding, these symptoms were relieved in a few hours.

A few years since a cooper lost the index finger of his left hand by sloughing from having

a cut in the finger, and happening to bring it in contact with one of the medusæ.

The poisonous property seems not to be confined to any particular part of the animal, as the fishermen frequently complain of having their faces blistered by small pieces of the animal being squirted into them when they are hauling their nets, and the medusæ entangled in them.

If you think these facts worthy of a place in your journal, by giving them insertion you will greatly oblige,

Yours respectfully,
Roseheart, Aug. 23. W. WISLEY, M.D.

GOSSIP OF THE WEEK.

WAR-OFFICE, Sept. 3.—12th Foot: Assist.-Surg. Peter Mackey, M.D., from 9th Foot, to be Assist.-Surg., vice Heffernan, appointed to 17th Foot.—17th Foot: Assist.-Surg. Nesbitt Heffernan, M.D., from 12th Foot, to be Assist.-Surg., vice Thomson, promoted in 69th Foot.—67th Foot: Assist.-Surg. John Samuel Charlton, from 63rd Foot, to be Surg.; Assist.-Surg. John Henry Dundas, from 52nd Foot, to be Assist.-Surg.—69th Foot: Assist.-Surg. John Bathurst Thomson, M.D., from the 17th Foot, to be Surg.; Arthur Stewart Willocks, gent., to be Assist.-Surg.—76th Foot: Assist.-Surg. Henry Cooper Reade, from the Staff, to be Surg.; James Crerar, gent., to be Assist.-Surg.—Hospital Staff: Assist.-Surg. William Rutherford, M.D., from the 62nd Foot, to be Assist.-Surg. to the Forces, vice Reade, promoted in the 76th Foot.

THE PASSENGERS ACTS.—It having been deemed expedient that the act of the 10th and 11th Victoria, cap. 103, which was passed in the last session of Parliament, to amend the act of 5 and 6 Victoria, cap. 107, for regulating the carriage of passengers in merchant vessels, should, as well as the last-named act, be delivered to the masters of ships for the information of the passengers, and that for this purpose the two acts should be printed together, and issued in lieu of the publication of the act 5 and 6 Victoria, cap. 107, forwarded to the collectors and controllers at the several ports of the kingdom in the month of October, 1842, those officers have received a notification from the Commissioners of the Customs that a supply of the new publication will be forthwith transmitted to their respective ports, and that they are to take care that the provisions of the acts be duly carried into effect so far as they are concerned.

DISCOVERY OF ANCIENT RELICS.—In digging through the Castle-hill for the continuation of the Ely and Huntingdon Railway to the Great Northern, the workmen, a few days ago, threw up a very perfect skull and several bones, as also a piece of iron having the appearance of a spear head, and a coin or two; it is most likely as they advance towards the centre some other relics of a bygone age will be discovered. About forty years ago, a human skeleton in a stone coffin was dug up on the hill where the windmill stands. Of the foundation-walls of the castle itself, no traces have as yet been found; great part of the hill through which the line has yet advanced is of a fine gravel soil, and appears never to have been disturbed. It may be interesting just now to know that the castle must have been of a very early date, for it is stated, on the authority of Camden, that in the year 917 King Edward the Elder built it anew; and David the Scot, to whom King Stephen gave the borough, about two hundred years afterwards enlarged it with many works, and from its commanding eminence and position it must have been a place of great strength, and the river running at its base rendered it easily surrounded with water; the outline of the deep fosse or ditch being still clearly discernible. It was utterly destroyed by Henry II., not only from its having become a retreat for seditious rebels, but from the frequent contentions for its possession between the Scots and the family of St. Lize, to whom it once belonged. It is probable that this destruction took place about 1176, having been surrendered to the

THE MEDICAL TIMES.

King in person in 1174: for in the former year Henry caused most of the castles which had belonged to the rebel barons to be dismantled or levelled to the ground. Some of the fragments were standing in the time of Speed the historian, about four hundred years afterwards.—*Cambridge Independent Press*.

SINGULAR MAGNETIC ATTRACTION OF MUD.—Sir A. Mackenzie was the first to notice the attractive power of the mud at the bottom of some of the lakes of North America, which is sometimes so great that boats can with difficulty proceed along the surface. This extraordinary fact is thus stated:—"At the portage or carrying-place of Matroses, on Rose Lake, the water is only three or four feet deep, and the bottom is muddy. I have often plunged into it a pole twelve feet long, with as much ease as if I merely plunged it into the water. Nevertheless this mud has a sort of magnetical effect on the boats, which is such that the paddles can with difficulty urge them on. This effect is not perceptible on the south side of the lake, where the water is deep, but it is more and more sensible as you approach the opposite shore. I have been assured that loaded boats have often been in danger of sinking, and could only be extricated by being towed by lighter boats. As for myself, I have never been in danger of foundering; but I have several times had great difficulty in passing the spot with six stout rowers, whose utmost efforts could scarcely overcome the attraction of the mud. A similar phenomenon is observed on the Lake Zagana, where it is with difficulty that a loaded boat can be made to advance, but fortunately the spot is only 400 yards over." This statement has received confirmation from Captain Back and others during the arctic land expeditions.

BOTANICAL SOCIETY OF LONDON.—Friday, September 3.—J. E. Gray, Esq., F.R.S., president, in the chair. Donations to the library were announced from Dr. Steele and the Rev. G. H. Stoddart. British plants had been received from Dr. Dickie, Dr. Dewar, Mr. Pitt, and Mr. Maw. Mr. Alexander Irvine, of Guildford, Surrey (honorary secretary of the Surrey Natural History Society), and Mr. G. Maw, of Richmond, Yorkshire, were elected members. Mr. James Hussey presented a specimen of the *Phalaris* from a field near Swanage, Dorsetshire, found by him in July last, reported as *Phalaris utriculata* (Linn.) in "The London Journal of Botany," September, 1847, but which Mr. Hewett Watson considers to be perhaps rather *Phalaris paradoxa* (Linn.), of which he possesses no authentic specimen for comparison with the Dorset example. Mr. Borrer presented a specimen of *Malva verticillata* (Linn.), (see "Phytologist," vol. 2, p. 934). Read "Description of *Hieracium heterophyllum*" (Bladon's MSS.), by Mr. James Bladon.

EFFECTS OF COFFEE ON SULPHATE OF QUININE.—M. Desvovues having made known the fact that an aqueous infusion of roasted coffee destroyed the bitter taste of sulphate of quinine (a fact, by the by, which has been long known in Martinique and elsewhere), M. Martin was of opinion that some investigation should be had on the nature of the reaction of these two substances on each other, before medical men employed coffee as a vehicle for quinine, and, accordingly, made some experiments on them. On mixing the quinine in powder with coffee a reaction was instantly caused; part of the sulphate of quinine united with the tannin of the coffee, with which it formed an insoluble compound; another portion of the salt mixed with the fatty oil and vegetable extractive into a pasty mass; and a third portion combined with the free acids always found in infusion of coffee. M. Martin found that coffee was not the only infusion that precipitated the solutions of sulphate of quinine; tea also formed insoluble compounds with it, and a marked difference could be perceived in the action of this mixture from that of infusions of indigenous plants. The infusion of tea of good quality contains much tannin, as is shown by a few drops of a solution of sulphate of quinine,

while the precipitate is almost nothing when added to adulterated tea.—*Journ. de Chimie Médicale*.

WEATHER PREDICTIONS.—Every one who is dependent on the weather for success in his calling, whether it be in the garden or the farm, must hail with delight any approach to correct predictions respecting it. The principles of astrometeorology, as explained by Mr. White, and his predictions founded thereon, have corresponded, in most instances, if not in all, with the actual state of the weather; and no doubt many, like myself, entirely unacquainted with that branch of physical science, are beginning to think it may be possible to foretell, with tolerable certainty, the sort of weather we may expect for a season, or even seasons. The advantages of such predictions to the cultivator would be in no way inferior to the brilliant discoveries of chemistry, or the vital and important knowledge which physiology discloses; for, looking at the nature and composition of vegetable substances, and also the nature and composition of the surrounding atmosphere, we see at once how much the vegetable substance is dependent on the surrounding atmosphere for its growth and perfection. If, then, the state of the atmosphere can be predicted, on sound scientific principles, what a glorious field lies open for the exercise of talented scientific minds! Is it too much to hope that science, assisted by data and experience, may yet be able to benefit mankind, in no small degree, by predictions that can be relied on? How many erroneous ideas would thus be dispelled; and one more proof would be added to man's knowledge of the infinite power, wisdom, and goodness of the Great Author of all things.—*J. Gray, Datchet; Gardeners' and Farmers' Journal*.

THE CRATER OF ETNA.—The main crater is about five hundred feet deep at this time. So say the guides; but I think this must be measured down the slope of the funnel. I could not, however, see to the bottom, owing to volleys of sulphureous smoke whirling up ever and anon, accompanied by a rumbling noise, and occasionally by a slight vibration of the ground underfoot. Here I found amidst warm ashes, on the slope of the crater within, heavy crystals of ice set all at one angle, and curved like sharks' teeth. I picked up one bit as big as a walnut, and asked the guide if he could account for its presence. Far be it from him to give a "rationale" of any thing of the sort: it would derogate from the dignity of Etna. It reminded me of a chemical experiment played off by a French savant at one of the late "Scienziati" meetings. He made water freeze in a red-hot cup. The silver of platina being brought to a red heat, a few drops of water are thrown in, which do not evaporate, but jump about. Sulphuric acid is now poured in, which, in the act of boiling, produces so intense a cold by the disengagement of its latent heat that the drop of water at once turns to ice. I opine the chemical process here to be the same, only on nature's grand scale. The morning mists supply the moisture, and within the crater there is no lack of sulphureous mixture boiling as in a retort; hence, as hot fumes ascend, the crystals of ice are precipitated. If any one reject this solution of mine, let them find a better, remembering that they are to account for pieces of ice forming on a bed of warm ashes. This principle of disengagement of latent heat may also help to account for the severity of the cold felt on Etna, which is far greater than is due to its elevation. I believe the summit of an Alp at the same level is not so cold, though in a more northerly latitude. A Russian, who ascended the mountain a fortnight before I did, was perfectly amazed: he said he never felt, even in St. Petersburg, such peculiar sensations of cold. There lay another smaller crater not far off, with a coudron of flames at its bottom; but the sides of this cannot be descended with safety. We paced a few yards down the interior of the big one, but I was never fond of breathing sulphur matches, so did not go far.—*Francis's Italy and Sicily*.

Some very curious experiments were performed a few days ago in the gardens of a gen-

tleman residing in the road to the north of the Regent's-park, by Mr. Milton, of Great Marylebone-street, who is well known as the author of "The Practical Beekeeper," by the application of ether to beehives, in order to reduce the bees to a state of stupefaction whilst the comb and honey were removed. The apparatus used was very simple. The ether was placed in a vessel, to which a flexible tube was affixed which was introduced beneath the hive (a one) through a small hole in a platform on which the hive was placed. The glass vessel was then placed in a larger vessel of warm water, by which the vapour was subtilized. In seven minutes the vapour completely stupefied the bees, who fell inanimate to the bottom of the hive. The hive was then removed. The atmospheric air revived the bees in about ten minutes, and in a short time after they were fully recovered. The same effects were then produced by the fumes of burnt nitre in another glass hive. The stupefaction of the bees was more immediate, but they recovered likewise on exposure to the atmospheric air. Another experiment was tried on a third hive, by igniting the species of dried fungus called a "powder-puff," and the result was similar. The use of ether, however, appeared more tractable, the strength being more capable of regulation than that of either the nitre or the "powder-puff." It was, moreover, more cleanly, and less likely to occasion accidents. The honey is not likely to be affected by the vapour of ether. It is so extremely volatile that its powers are dispersed by the atmospheric air almost immediately. The great advantage is the simplicity as well as the efficacy of the application, and all apianians will acknowledge themselves indebted to Mr. Milton for his introduction of a mode of obtaining honey, and at the same time of preserving the bees, superior to any yet made use of.—*Times*.

OBITUARY.—At Spa, on the 29th ult., aged 61 Thomas Beard, Esq., M.D., formerly of the Royal Regiment of Artillery. He died universally respected and lamented, after a residence in the above town of 21 years.—Aug. 12th, at Ormskirk, much and deservedly respected and regretted, aged 66, Mr. Ed. Houghton, surgeon, for upwards of forty years senior surgeon to the Dispensary.

MORTALITY TABLE.

For the Week ending Saturday, Sept. 4, 1847.

Causes of Death.	Total.	Average of 5 Summers.
ALL CAUSES.....	1051	940
SPECIFIED CAUSES...	1049	936
Zymotic (or Epidemic, Epidemic, and Contagious) Diseases.....	351	226
SPORADIC DISEASES.		
Droopy, Cancer, and other Diseases of uncertain or variable Seat.....	122	103
Diseases of the Brain, Spinal Marrow, Nerves, and Senses.....	138	157
Diseases of the Lungs, and of the other Organs of Respiration.....	202	226
Diseases of the Heart and Blood-vessels.....	27	26
Diseases of the Stomach, Liver, and other organs of Digestion.....	101	94
Diseases of the Kidneys, &c. Childbirth, Diseases of the Uterus, &c.	7	8

SUGGESTIONS

FOR A MORE SIMPLE ARRANGEMENT OF THE

MATERIA MEDICA,

BASED ON ITS PHARMACEUTICAL AND THERAPEUTICAL RELATIONS.

By GEORGE LEITH ROUPPELL, M.D.

Cantab., F.R.S., Fellow of the Royal College of Physicians, Physician to St. Bartholomew's Hospital, Lecturer on Materia Medica at the College of St. Bartholomew's Hospital.

(Continued from p. 564.)

LECTURE IX.

My third order of the organic materia medica is composed of Drugs which owe their Efficacy to Astringent Matter.

These drugs are all derived from the vegetable kingdom, and produce marked and characteristic effects. They corrugate the tongue, and give a peculiar sensation of harshness and roughness to the palate. They check excessive discharges from the body during life, and after death toughen and solidify, and, as is well known, tan certain of the tissues.

M. Cavarra, indeed, maintains that the vegetable astringents act in the same way upon the living as upon dead animal matter, checking the discharges by condensing the solids, thus diminishing the calibre of vessels, contracting the muscular fibre, and producing a shrinking of the mucous membranes, which impedes the secretion from their glands. Modern chemistry has shown that this astringency is due to certain principles largely abounding in various parts of plants, but especially in the root and bark. These are tannin and gallic acid.

Tannin, the symbol of which is \overline{Qt} + 3 aq., and formula $C^{18}H^8O^8$, is usually prepared by macerating gallnuts in ether, separating the heavier portion of the fluid, and drying the precipitate. It appears in masses of a yellowish colour, without odour, very soluble in water, and of an intensely astringent taste, having an acid reaction. It precipitates most of the organic alkalis, the carbonated mineral alkalis, tartar emetic, and gelatine, and strikes a green or a bluish-black colour with the persalts of iron. M. Pelouze states that in doses of three or four grains it produces vomiting, but that two or three grain doses cure leucorrhœa, gonorrhœa, and the most obstinate catarrhs; control hemorrhage from the uterus, hemoptysis, diarrhœa, and are useful in phthisis.

Gallic acid, more commonly employed in this country, is prepared by exposing tannin to the action of atmospheric air, or to that of either acids or alkalis, aided by heat, or by evaporating and purifying the lighter portion of the fluid when gallnuts are macerated in ether. When thus obtained, pure gallic acid crystallizes in brilliant white prisms, soluble in both water and alcohol. It blackens the persalts of iron, but does not precipitate gelatine. Gallic acid, in doses of from one to five grains, is of use in

passive discharges, whether of blood, mucus, or perspiration.

I shall divide this class into two orders—those which precipitate the persalts of iron of a green colour, and those in which the precipitate is of a bluish-black. This difference in colour is sufficiently marked. There are, however, other differences: in the first place, the tannin in these is nearly free from gallic acid; and in the second, it appears that the precipitate formed with albuminous substances varies, according to M. Mialhe, in several important particulars. We have, then, to consider—

39. Tannin α , precipitating persalts of iron green, as contained in—

Acacia catechu.
Uncaria gambir.
Pterocarpus erinaceus.
Cinchona.
Krameria triandria.
Coffee arabica.

39. Tannin β , precipitating persalts of iron of a bluish-black colour, as obtained from—

Quercus infectoria.
Quercus pedunculata.
Ulmus campestris.
Tormentilla erecta.
Uva ursi.
Rosa gallica.
Punica granatum.

IV. Drugs which owe their Efficacy to Fixed Oil or Fatty Matter.

Oily substances or fatty matters are obtained both from the animal and the vegetable kingdoms. It will not be necessary at this time to prove the identity of the principles thus obtained.

These substances are important in dietetics, in pharmacy, and therapeutics.

The absorption of fatty matters would appear to be due to the action of the alkalis in the intestinal canal; if given in larger quantity than can be acted upon by these secretions, they would seem to traverse the alimentary tube, lubricating it, and gently exciting the peristaltic movements. Given too long, oils are said to congest the liver, the kidneys, and the lungs, and to occasion concretions like cholesterine in the bowels. Some of the oils are actively aperient. The changes which result on the combination of alkalis and certain metallic oxides with fatty matters are pharmaceutically important. The action of alkalis, regarding oils and fat as the union of certain organic acids with the oxide of glycerule, is to

decompose this compound, the alkali uniting with the acid, and liberating the oxide of glycerule. The acids are the stearic, the margaric, and the oleic. The compounds of the oxide of lead with the oleic and margaric acids form the basis of almost all medicinal plasters.

Oils may be divided into two classes, drying and fatty:—

40. Oils α , drying, obtained from—
Linum usitatissimum.
Croton tiglium.
Ricinus communis.
Jecur aselli.

40. Oils β , fatty, obtained from—
Amygdalus communis, amara.
Olea europea.
Laurus filix mas.

40. Fats α , obtained from—
Lauri baccæ.
Theobroma cacao.
Myristica moschata.
Avoira elais.
Sus scrofa.
Ovis.
Physeter macrocephalus.

40. Fats β , obtained from—
Moschus moschiferus.
Castor fiber.
Apis mellifica.

V. Drugs which owe their Activity to Resinous Matter.

Resins abound largely in, if they do not belong exclusively to, the vegetable kingdom. They are found deposited in wood or dissolved in essential oils. Resins vary much in their characters. Some are hard, others soft; some soluble in alcohol and ether, others are insoluble in these menstrua. A certain number have the properties of acids, others again are neutral and do not combine with bases. The acid resins decompose the carbonated and dissolve in caustic alkalis. According to the most modern view, resins are first acted upon by the alkaline secretions in the intestinal canal previous to their absorption. The compound formed by the union of an alkali with a resin is called a soap, but it differs in several respects from a true soap. Resins may be generally described as solid substances, brittle, semi-transparent, coloured; bad conductors of heat, and non-conductors of electricity. They are heavier than water, are composed of oxygen, hydrogen, and carbon, are easily inflammable, burning with a smoky flame; they soften in boiling water, but require a higher temperature to melt them.

They are soluble both in fixed and volatile oils, and in combination with various substances, both organic and inorganic, constitute our plasters.

Fossil resins, there can be little doubt, are derived from extinct vegetation.

I shall assume, as a basis for subdivision of this class, certain natural combinations; such, for example, as that of an essential oil; gum in addition to an essential oil; and still further, in addition, benzoic acid, forming the true balsams.

41. Resin α , as contained in—

Guaiacum officinale.
Pistacia lentiscus.
Euphorbium officinarum.
Daphne mezereum.
Uspicum annuum.
Polygala senega.
Pomacea purga.
Convolvulus scammonia.
Cannabis sativa.

41. Resin β , as contained in—

Pinus plauris, balsamea, sylvestris.
Abies excelsa.
Pistacia terebinthus.
Copifera multijuga, &c.
Piper cubeba, nigrum, longum.
Boswellia serrata.
Amyris elemifera.
Zingiber officinale.
Anacardium pyrethrum.
Canella alba.
Succinum.

41. Resin γ , as contained in—

Hebradendron gambogioides.
Balsamodendron myrrha.
Ferula asafoetida.
Sagapenum.
Galbanum officinale.
Dorema ammoniacum.

41. Resin δ , as contained in—

Rhus toxicodendron?
Styrax benzoin, officinale.
Myroserpium perulfiferum et toluiferum.

Under the head of resins it may be remarked that I propose to treat of the various products of heat upon this class of bodies, with other vegetable juices, as exemplified in the combustion of pine wood in the manufacture of tar. This will include the preparations of tar, petroleum, creosote, &c.

The sixth class in my arrangements is composed of

VI. Drugs which are chiefly Active, through the Presence of an Essential Oil.

Essential oils are principles with marked properties, have an odour more or less agreeable, a pungent, acrid taste. They are highly inflammable, their vapour taking fire on the approach of a burning body. They abound in vegetables, almost all parts of which occasionally secrete them; the seed, however, and the flower, with the leaf especially, contains them. Distillation and pressure are the means by which the essential oils are procured, some of which are lighter, others heavier, than water. They are mostly fluid, but in some few instances appear in a solid form. By exposure to the air they become converted into a resin by the absorption; the idea, however, formerly entertained, that essential oils were resins imperfectly oxidized, is not now considered as tenable; still they are often combined in nature, as has been already shown. They vary in composition: some contain oxygen, hydrogen, and carbon; others contain no oxygen; a few are differently composed, as the oil of bitter almonds or of mustard. They are all soluble in alcohol, ether, and fixed oils, and they are soluble to a certain extent in water. Taken internally, they are powerful stimulants; applied to the skin, they quickly excite the vessels, are rubefacients and vesicants. The blistering principle of the cantharides would appear to have its nearest alliance with the essential or volatile oils. The principal sources of these bodies not yet alluded to are—

42. Essential oil α , as obtained from—

Ruta graveolens.
Cochlearia armoracia.
Origanum vulgare.
Cuminum cyminum.
Rosa centifolia.
Mentha piperita, sativa, pulegium.
Lavandula spica.
Rosmarinus officinalis.
Pimpinella anisum.
Anethum graveolens.
Feniculum dulce.
Coriandrum sativum.
Carum carui.
Daucus carota.
Melaleuca minor.
Cinnamomum zeylanicum, cassia.
Caryophyllus aromaticus.
Myristica moscata.
Eugenia pimenta.
Valeriana officinalis.
Sassafras officinalis.

42. Essential oil β , as obtained from—

Citrus medica, aurantium.
Juniperus communis-sabina.

42. Essential oil γ , as obtained from—

Asarum europæum.
Sambucus nigra.
Laurus camphora.
Cantharis visicetoria(?).

42. Essential oil δ , as obtained from—

Amygdalus amara.
Sinapis nigra.

I shall here conclude my proposed arrangement of the essential oils, and of substances allied to them. It is evident that the subdivisions have reference either to the chemical composition or to the aspect of the substance in question,—properties which it is important should be borne in mind, whether we regard the preparation of these bodies or their medicinal use.

A COURSE

OF

LECTURES ON SURGERY,

BY

SAMUEL COOPER, Esq., F.R.S.,

Professor of Surgery to University College, London.
Consulting Surgeon to London University Hospital, &c.

LECTURE XV.

GENTLEMEN,—In my last lecture I spoke briefly of boils; in some respects carbuncles are analogous to them. The appearance of the carbuncle is generally preceded by great heat and much pain in some parts of the body, and presently several vesicles arise, attended with a violent burning and itching pain. The base of this affection is very deep, and widely spread in the cellular tissue, so that where you have a superficial extent of two inches the base may measure six inches in diameter. Towards the centre it becomes of a dark red colour, but near the edges it is much paler. If allowed to go on for a time, the skin at the apex will rise, becoming at the same time very thin and easily broken, and, as the itching pain is excessive, it often is removed by the scratching of the patient. Out of the opening thus made a thin brown matter exudes, or a whitish matter tinged with blood, and an eschar is seen. The size of carbuncles varies very much. I have in my experience found them as large as an ordinary-sized dinner plate. They differ from boils chiefly in this, that it has no core in the centre, and instead of suppurating they progress very rapidly to a gangrenous termination under the skin; unlike boils, they generally attack the old, and these carbuncles have a peculiar feel, reminding one of brawn. Sometimes sloughing takes place very extensively under the skin when no sign of mortification can be seen. The constitutional disturbance is often very great, especially when the carbuncle appears in persons in a typhoid state; the patient is restless and pale, and complains of headache; the tongue is

very white, or else of a deep red. He is, perhaps, delirious, and has rigors, and a chilly feeling comes over him; he loses appetite, has difficulty of breathing, and is low and fainting. When the carbuncle occurs in old persons whose constitutions have suffered from excess, as is often the case, the disturbance becomes so great as frequently to endanger the whole system. Generally we may consider the danger to be in proportion to the size and locality of the tumour, their number, the age of the patient, and, of course, the state of the constitution. With respect to the treatment, the grand point is to promote the free escape of the sloughs and matter from the tumour at as early a period as possible. In order to this, a free incision must be made; and when this has been done, and time has been allowed for the detachment of the dead skin to advance, it will be advisable to complete the separation with a pair of scissors. Before the opening is made no applications are so beneficial as emollient poultices, and after the operation they are far better than the lotions and injections which some have employed. The poultices should be changed frequently, on account of the fetor of the discharge. When the sloughs have come away, and the internal cavity exhibits a red colour and granulates, the poultices may be discontinued, and a pledget of soft lint and some unirritating ointment should be substituted, secured by the compress and bandage.

The treatment of this disease does not consist in much bleeding or depletion, although I have seen leeches employed with advantage, and of course it is right to clear out the bowels with mild purgatives; but such is the prostration of the system, that tonics and stimulants are generally more in place. The local treatment is often more important than the general and constitutional. An early incision—crucial incision is of first importance; it gives quicker relief than any mere internal means can afford. Sometimes, too, you must support the constitution by bark, ammonia, camphor, wine, and ether; these are the principal medicines which the surgeon can resort to. You must not neglect diet; allow the patient to take wine and brandy now and then. When you have made the incision, you often find that the dead cellular tissue, which has so much to do with the maintenance of disease, will not readily come out, and you must then use a little pressure, but not, however, so much as to put the patient to immense pain; perhaps you will get it half out the first time, and the rest you must leave to the poultice. The best applications you will find to be warm emollient poultices. There are some who put confidence in local stimulants. Sir Astley Cooper was very partial to use oatmeal poultice mixed with port wine, to be used when the sloughs are slow coming out; and I do not deny that it may be very rational to employ these stimulents under some circumstances. If you see that a stimulant will be useful, you will not be at a loss to meet with one for your purpose; it is when the slough lies deep and the carbuncle is old that they will be most useful.

Another gangrenous inflammation is called the malignant pustule; it appears, at first, as a small vesicle, containing a bloody serous fluid, and under it is an induration which produces sloughs; it will destroy the cellular tissue and the soft textures of the body in twenty-four hours. It is not circumscribed like the boil, and is more typhoid; it is remarkable as occurring in persons who follow particular trades; and you will understand why this should be when you learn that it arises not like the carbuncle and boil, from internal causes, but from a specific contagion, such as from contact with cattle affected with contagious disease. Thus it is found in tanners, butchers, drovers, and shepherds, and those who have to do with cattle. Baron Larrey relates that, in the campaigns of the French army in Italy, the soldiers were attacked with it in consequence of eating the flesh of cattle which had been infected; it is, however, generally produced by contact of the poisonous substance at some part of the patient's

body, which is abraded at its external surface. A cook in skinning a hare may prick her finger, and this may be followed by what many excellent surgeons think is malignant pustule; but whether any infectious matter is introduced into the wound, or whether the bad consequences are the result of a bad habit of body, may be very doubtful. This is a kind of gangrene which does not admit of antiphlogistic treatment: for in the beginning the patient's strength is very low, and there are frequent syncopations coming on; the patient has pain about the region of the heart; coma and delirium are present, and the symptoms are most urgent and severe. The local treatment consists in making deep incisions, and in the application of strong caustics; and, where the pustule is small, it may be well even to excise it entirely: following this up by stimulating dressings. The best internal means are the exhibition of bark, quinine, dilute sulphuric acid, and other tonics and stimulants, together with opium.

There is one form of inflammation which is much more necessary to be treated of, because it is much more common: I mean erysipelas—a disease which often baffles the skill of the best operative surgeons. He performs his operation with the greatest dexterity, but afterwards inflammation comes on, spreads very fast, and great constitutional disturbance takes place. It is found that, in particular places, at different seasons of the year, persons are more liable to it than others. There are some wards in hospitals of this city which are notorious for the ravages of erysipelas. Every one who has been much at the Borough hospitals knows how much mischief has been done by erysipelas there. It is a disease of the skin, the cutaneous tissue, and the cellular membrane beneath; it is always characterized by a great deal of redness, and also by a disposition to spread, and in a very short time to cover a large surface.

It is divided into three varieties, and these have themselves been subdivided: they are, simple, phlegmonous, and oedematous erysipelas. It is a common question at the examination of the College of Surgeons—What is the colour of erysipelas? The answer is, that simple erysipelas is generally of a bright red, smooth and shining, but it differs in shade, though it is never so dark as in the phlegmonous kind. When we touch the parts a white spot is seen, which soon disappears, showing how quick is the circulation in the part. When a little time after you apply your finger, you perceive it has lost some of its suppleness; although the alteration may not be very great, yet it is plainly perceptible. The pain is a pricking and irritating sensation, which afterwards becomes an intense burning pain. Then, with respect to the redness, instead of being diffused, as in some other inflammations, it terminates abruptly, not fading away, as in the phlegmonous kind. About the third day vesicles make their appearance: they are small, though some cases have them larger; and about the sixth day these vesicles burst, and when they have discharged their contents scabs form in their place. It is the nature of erysipelas to spread very fast; but, though it will spread very much in one direction, it will at the same time be getting well in another; the skin peels off (for erysipelas ends chiefly in resolution), and another incrustation is formed, the pain of which is severe. You will find sometimes, when inflammation has been severe, suppuration taking place in some parts of the cellular tissue, and when the scabs fall off the skin is found in a healthy state. The constitutional disturbance is often severe, and sometimes fatal, even in simple erysipelas. The tongue is covered with white fur, and the pulse is quick and weak—weaker than in phlegmonous inflammation. The patient suffers with chills, and where it comes with fever, the rigor is very severe. If we except gout, mumps, and rheumatism, there is no other disease which attacks so suddenly other parts; it will frequently fasten upon the internal structure of the body.

With regard to the causes of erysipelas, I told

you that it was sometimes an effect of febrile disturbance of the whole system. We have found it following mechanical injuries and surgical operations baffling the skill of the surgeon. There are some parts of the surface more disposed to erysipelas than others; for instance, the skin of the face and covering of the head. At some periods of the year, too, we found that some patients are more liable to erysipelas than at others, and any operations which may be required at this season will be undertaken with reference to the disposition to erysipelas.

I attended a lady who had a tumour on the nose, which was rather a drawback upon her appearance. I told her she had better not have it taken out; she, however, went to Sir Astley Cooper, and he took it out at once in his parlour. She was attacked by erysipelas, and died in eight days afterwards. I removed a tumour once off the parotid gland, and, though the operation was easily performed, the patient died of erysipelas a week after. You are to remember, then, that the skin of the neck and face, and scalp, are especially liable to erysipelas, and surgical operations are frequently made void by this circumstance. Yet you must remember that, if these persons had not been in a bad state of health, they probably would not have been attacked with erysipelas. I was saying that it follows mechanical and chemical injuries; fractures, also, and exposure to cold draughts, will bring on erysipelas when the person is in a bad state of constitution. It is said that it is sometimes contagious: it is certainly endemic, prevailing in certain districts; but whether it is contagious is a question difficult to answer. Unprofessional persons have no suspicion of its being contagious, and these are generally ready to take up an alarm of that kind. There have been cases brought forward by acute observers in which they have believed they have had evidence of the contagious character of this disease. You will find a paper by Dr. Wells in the "Transactions" of the Medical and Surgical Society, in which the advocates this view; and certainly there is a difference of opinion on this subject. I attended two cases in the same house—a gentleman and his servant—but whether the second case was brought on by infection, or by breathing the same air and living on the same diet, it is hard to say.

ON THE PHYSICAL PHENOMENA OF LIVING BODIES.

By Professor MATTEUCCI, of Pisa.

PART XV.

CIRCULATION OF THE BLOOD.

The blood is of a bright vermilion tint in the arteries, of a dark red colour in the veins; it is a slightly alkaline liquid of from 1.0527 to 1.067 specific gravity, and holding in suspension globules of greater or less diameter; these globules are circular in the great majority of mammifera, and of elliptical shape in birds, reptiles, and fishes.

The quantity of the blood varies in the different classes of animals, and its weight seems to stand in a certain ratio to that of the animal. Valentin has given us the following ingenious method to determine the total quantity of the blood:—Withdraw a small quantity of blood from an animal by means of venesection, and determine the exact proportion between 100 parts of the water and the solid matter of the blood. Insert now a given weight of water into one of the bloodvessels of the animal, and determine subsequently, again, the proportion between 100 parts of the water and the solid matter of the thus diluted blood. From these data the total quantity of the blood may be readily calculated.

The quantity of blood contained in the human body amounts, on an average, to from twelve to fifteen kilogrammes, which is to the weight of the body as 1:5.

The heart of an adult contracts from seventy to seventy-five times per minute; the number of pulsations varies with the age, the sex, the con-

stitution, individual idiosyncrasy, the class to which the animal belongs, and the pressure of the atmosphere. Thus, we found from 180 to 140 pulsations in new-born infants; from 20 to 24 in fishes; 60 in the frog; from 100 to 140 in birds. Parrot found the number of his pulsations amount to 110 per minute, at an elevation of 4000 metres above the level of the sea, instead of 70, the usual number with him on the level, or but slightly above it.

We now come to the velocity of motion of the blood. The researches made on this subject may be divided into two categories, viz.—1, as regards the time which the blood takes to pass through the whole of the circulatory system; and 2, as regards the respective velocity with which the blood passes through the various organs constituting this system, viz., the arteries, the capillaries, and the veins. Hering, Poiseuille, Piria, and the author have made several experiments to determine the velocity with which the blood passes through the whole of the circulatory system. These experiments were made as follows:—A solution of prussiate of potass was injected into one of the jugular veins of a horse, and blood drawn at the same time from the opposite jugular: the blood drawn was found to contain traces of this salt from twenty to twenty-five seconds after injection. Poiseuille observed, in the course of his experiments, that the injection of the prussiate of potass, and certain other substances, causes no variation in the number of the pulsations nor in the force of the contractions of the heart; mixing the prussiate of potass with solution of acetate of ammonia, he found traces of the former salt in the blood after eighteen seconds; mixing it with nitrate of potass, he found the prussiate after twenty seconds; the addition of alcohol, on the contrary, retarded the appearance of the prussiate by about twenty seconds. Poiseuille has ascertained, in the course of important researches on the flow of liquids, such as water, serum, &c., in the capillaries, that these substances act in the latter absolutely as in the circulatory process, which shows that it is upon the velocity with which the blood passes through the capillaries that the action of the alcohol, nitrate of potass, and acetate of ammonia is exercised. It would be a great mistake, however, to suppose that it is by any influence of this description that many other substances introduced into the circulatory current act: many of them exercise their action upon the nervous force, and thence upon the contraction of the muscular fibre of the heart; thus a small quantity of infusion of coffee injected into the veins of a dog suffices to augment instantly the force of the cardiac contractions, whilst the injection of solution of opium, on the other hand, diminishes the energy of these contractions.

The author thinks that Hering's method of determining the velocity of the circulation is liable to objection, although the results obtained by this method are generally adopted as correct. The author thinks it would be more satisfactory if a small solid body of the same density with blood could be introduced into the one jugular, and should make its reappearance at the opening of the other. We know that two fluids susceptible of intermixing do so rapidly, and without the aid of motion; and that, though but a small quantity of one fluid be added to a large amount of another fluid, the presence of the former is very speedily detected in the whole mass of the mixture. Moreover, the injection of a fluid into the vessels is effected by means of a pump, and with considerable force, to overcome the opposing pressure of the blood; and we find that the intermixture of the injected fluid with the mass of the blood is promoted in direct ratio to the degree of force applied.

But we have another and more exact means to measure the velocity of the circulatory current, viz., the method of Hales, which deduces this velocity from the capacity of the ventricles and the number of cardiac pulsations in a given period of time.

Hales measured the capacity of the left ventricle of the heart of the horse and other animals;

he found it to be of ten cubic inches, English, in the heart of a young horse; the weight of one cubic inch of blood being 267 grains, it results that the total weight of blood contained in the left ventricle is about six ounces. Assuming the ventricle to void itself entirely at each pulsation, there would thus be six ounces of blood expelled at every contraction, and it would, accordingly, require seventy-two contractions to accomplish the circulation of the thirty-six pounds of blood contained in the body of the horse. This gives a very different result regarding the velocity of circulation from that found by Hering: the heart of the horse making sixteen pulsations in twenty-five seconds, no more than eight pounds of blood are expelled in that time from the ventricle. It would be difficult to account for this marked difference in the result, were we to admit the correctness of Hering's figures.

Hales gives the following numbers:—Taking seventy-five as the number of pulsations per minute in adults, and from twenty-four to thirty pounds the weight of the total mass of the blood, and about two ounces as the amount expelled from the left ventricle at each contraction, it would require 192 pulsations, or about two minutes and a half, to accomplish the circulation of the whole mass. And even these figures are below the correct ones, as we can hardly admit that the whole of the blood contained in the ventricle is expelled at each pulsation.

We now come to the second point, viz., the respective velocity of the circulation in the different classes of vessels constituting the circulatory system. Assuming the section of the orifice of the left ventricle to be the same with that of the aorta, and the sum total of the sections of the several ramifications into which the aorta is divided, to give the same number, the same quantity of blood passing thus everywhere in the same space of time, the velocity would be equal in each vessel. But this assumption is not correct for the sections of the arterial and venous trunks, and the sections of their ramifications. The most simple observation suffices, on the contrary, to demonstrate that the sum of the sections of the small vessels, exceeds that of the sections of the large trunks. Thus the author found the diameter of the orifice of the aorta, in the heart of the ox, = to about 28 millimètres; that of one of the trunks = to 20 millimètres; and that of the other trunk = to 16 millimètres, while the venæ cavae were found to have a total diameter of 76 millimètres. The well-known law of Castelli is to be applied to calculate the respective velocity of the blood at the several stages of the circulation; this velocity will invariably be in inverse ratio to the sections. If we could correctly and rigorously appreciate the proportions which the sections of the several vessels bear respectively to one another, it would be easy to determine the respective velocity of the blood in the several classes of vessels, provided we knew exactly the quantity of the blood expelled at each contraction by the left ventricle and the time employed in the expulsion.

We shall confine ourselves here to give an example how to determine the velocity with which the blood passes through the aorta; we adopt the figures given by Hales. The amount of blood expelled from the left ventricle of a horse is about ten cubic inches; the section of the aorta being about 1.036 square inches, the fraction $\frac{10}{1.036} = 9.65$ expresses the length of the column of blood penetrating into the aorta at every systole of the heart; and, as the number of cardiac pulsations in the horse is 36 per minute or 2160 per hour, it follows that the column of blood thrown into a tube of the same diameter as the aorta would be, at the end of one hour, 167 feet long. Considering that the systole lasts only one-third of the space of a pulsation, we have to multiply this by three, which gives a velocity of 83.5 English miles per minute. Hales has endeavoured to determine experimentally the velocity of circulation in the capillaries. For this purpose he introduced warm water into the descendant aorta of a dog (by means of a long glass tube pushed into the

artery). The pressure exercised by the liquid column was about equal to that which the blood has to support in this vessel. An intestine being laid bare and cut, the water was seen oozing out drop by drop from the capillaries. He varied the experiment, by dividing the vessels, approaching nearer and nearer to the aorta, and measuring at the same time the amount of water running in a given time from the several capillaries, of which he knew the diameter. The ressure of the liquid column was maintained constantly at the same point. The following are some of the resulting numbers:—342 cubic inches exuded from the capillary vessels in 400 seconds; from the mesenteric arteries the same quantity ran off in 140 seconds; from the crural arteries in 20 seconds. Although these figures do not by any means show the absolute velocity with which the blood passes respectively through the different vessels, yet they demonstrate clearly how much this velocity diminishes in proportion as the vessel is more distant from the heart. Notwithstanding the marked excess of the sum total of the sections of the branches over that of the trunks, it is certain that the circulation decreases in velocity, and proceeds on more slowly, than it would if all the partial sections were united into one vessel. This decrease in the velocity of the circulation is owing to the friction of the fluid against the walls of the vessels, the large folds, the numerous bends, and the resistance of the liquid column to the motion imparted to it.

The capillary circulation of the lungs of the salamander, and of the mesenterium and foot of the frog, may be studied under the microscope: the globules of the blood are seen to move with greater or less rapidity in the interior of the small vessels, in proportion as the section of the latter is greater or smaller.

(To be continued next week.)

DUMAS ON ORGANIC CHEMISTRY.

No. XXX.

(Continued from page 568.)

THE BONES.—(continued).

THE TEETH.—The different parts of which the teeth are composed—the enamel, the dental bone, and the cement—present a composition very analogous to that of bone.

The enamel is a hard, smooth, and shining substance, which surrounds the dental bone as a kind of coating; this may be detached from the tooth by drying it at a temperature of 120° C. It contains more earthy salts than the other parts of the tooth. M. Berzelius analyzed the enamel of the human tooth and that of the tooth of the ox; the following are the results he obtained:—

	Enamel of man.	Enamel of the ox.
Phosphate of lime with fluoride of calcium	88.5	85.0
Carbonate of lime	8.0	7.1
Phosphate of magnesia	1.5	3.0
Soda	—	1.4
Brown membrane adherent to the dental bone, alkali, water, &c.	2.0	3.5

100.0 100.0

The dental bone forms the interior part of the crown and of the root; it is hollowed in the centre by a canal destined to receive the vessels and nerves which serve for the nutrition of the tooth. Its anatomical structure is analogous to that of bone, from which it is distinguished, in respect to its chemical composition, solely by a somewhat more considerable proportion of earthy matters. According to Berzelius, dental bone possesses the following composition:—

	Man.	Ox.
Cartilage and vessels	28.0	31.00
Phosphate of lime with fluoride of calcium	64.3	63.15
Carbonate of lime	5.3	1.38
Phosphate of magnesia	1.0	2.07
Soda with a little chloride of sodium	1.4	2.40

100.0 100.00

The root and that part of the tooth which is simply covered by the gum, and which we call the neck, are surrounded by the cement, a peculiar osseous substance, of which the composition greatly resembles that of bone, properly so called. According to the analysis of M. Lassaigue, the cement contains:—

Animal matter	42.18
Phosphate of lime	53.84
Carbonate of lime	3.98

100.00

M. Lassaigue has made some extended researches on the composition of the teeth in animals. The following are the results which he has obtained:—

Teeth.	Organic matters.	Phosphate of Lime.	Carbonate of Lime.
Of an infant, a day old	35	51	14
Of a child, 6 years of age	28.67	60.01	11.42
Of an adult man	29	61	10
Of an old man, 81 years of age	33	66	1
Of an Egyptian mummy	29	55.5	15.5
Front teeth of a rabbit	31.2	59.5	9.3
Molars of a rabbit	28.5	63.7	7.8
Molars of a wild boar	29.4	63	8.8
Tusks of a wild boar	26.8	69	4.2
Tusks of a hippopotamus	25.1	72	2.9
Molars of a horse	29.1	62	8.9
Fore teeth of a horse	31.8	58.3	10
Fore teeth of an ox	28.6	61	8
Teeth of an adder	30	70.3	3.7
Poison fang of a viper	21	73.8	5.2
Teeth of a carp	35	49	16
Teeth of a shark	33.6	52.6	13.0

SHELLS.—Most insects are covered by a shell of considerable hardness, which is principally formed of a substance to which M. Odier has given the name of *chitine*. We also meet with this substance in the *elytra* of the *coleoptera*. These organs must be acted on by a solution of caustic potash, which removes their albumen, extractive matters, and a coloured fatty matter, when there remains the *chitine* which forms a fourth in weight of the *elytra*. This substance is dissolved in dilute sulphuric acid, and by the aid of heat, in nitric acid, forming a colourless solution. When exposed to a strong heat, it carbonizes without melting, or without yielding any ammoniacal products.

Hatchett found, in the shell of the insect, a considerable quantity of phosphate and of carbonate of lime, besides 26 per cent. in weight of a clear, yellow-coloured, animal substance, similar to cartilage.

The shell of the crawfish contains a peculiar colouring matter which has the property of reddening by boiling. According to MM. Macaire and Lassaigue, this substance may be isolated by acting on the shell by alcohol, and then evaporating the solution. There remains a red matter of a fatty appearance, insoluble in water, but very soluble in alcohol, ether, and in the oils. Caustic potash in like manner dissolves it, but does not form a soap with it. According to an analysis of M. Goebel, this fat is composed of 68.18 carbon, 9.24 hydrogen, and 21.58 oxygen. The same chemist found in the claws of this fish:—

Carbonate of lime	68.36
Phosphate of lime	14.06
Animal matter	17.88

According to M. Chevreul, the shells of the lobster and of the crab are formed of:—

	Lobster.	Crab.
Animal matter	44.76	28.6
Salts of soda	1.50	1.0
Carbonate of lime	47.26	62.8
Phosphate of lime	3.82	6.0
Phosphate of magnesia	1.26	1.0

Shell of the Oyster.—MM. Bucholz and Brandes give the following as the composition of this shell:—

Insoluble animal matter	0.5
Carbonate of lime	98.6
Phosphate of lime	1.2
Alumina (accidental)	2.0

Oyster shells are formed of nearly pure carbonate of lime: they may, consequently, be employed in the preparation of caustic lime; only, it sometimes happens that lime, thus prepared, besides some traces of phosphate, will also contain a little sulphuret, of calcium, arising from the sulphur of the animal matters.

BRAIN.—The brain is the nervous centre of the superior animals. We divide it into the *cerebrum* and the *cerebellum*. The cerebrum occupies the whole of the anterior and the postero-superior part of the cranium; the cerebellum occupies the postero-inferior part, and, in the adult man, constitutes scarcely the eighth part of the entire brain. The surface of the brain is uneven, and presents projections which have been denominated convolutions. When the brain is cut, we remark that the substance of which it is composed is not homogeneous, but that it is formed of grey and of white layers, which have been designated as the cortical and the medullary substance.

Vauquelin published, in 1812, "An Analysis of the Human Brain," which he found composed of:—

Water	80.00
White, crystalline, fatty matter (stearine)	4.53
Reddish, unctuous, fatty matter (oleine)	0.70
Albumen	7.00
Animal matter	1.12
Phosphorus	1.50
Acids, salts, and sulphur	5.17

100.00

M. Lassaigne has arrived at results very similar to the foregoing; only, he made separate analyses, first, of the entire brain, then, of the medullary, and, finally, of the cortical substance. Annexed are the principles which he met with in the brain of an idiot:—

	Entire Brain Substance.	Cortical Substance.	Medullary Substance.
Water	77.0	85.0	73.0
Albumen	9.6	7.5	9.9
Colourless fatty matter	7.2	1.0	13.9
Red fatty matter	3.1	3.7	0.9
Extractive matters	2.0	1.4	1.0
Lactates	1.1	1.2	1.3
Phosphate of lime	1.1	1.2	1.3
Magnesia; oxide of iron			

100.0 100.0 100.0

John had previously remarked that the fatty matters predominated in the medullary substance. M. Chevreul was the first to point out the existence of cholesterine in the brain.

M. Couerbe, also, has endeavoured to isolate some of the fatty matters contained in the brain, and he has admitted the existence, in this organ, of the four following bodies:—

Stearocerate, a yellow, pulverulent, fatty principle.

Cephalote, a yellow, elastic, fatty matter.

Eléencephol, a reddish-yellow oil.

Cerebrate, the white matter of Vauquelin.

M. Frémy has pursued the same line of investigation, but he has adopted more perfect means of separation; the results of his analyses, though somewhat different to the foregoing, seem to be nearer to the truth. He has, at the same time, shown that the matters studied by M. Couerbe were mixtures, and not pure matters. The cerebral mass, according to M. Frémy, is formed by an albuminous matter mixed with various substances of a fatty nature; he found that the human brain contains:—

Water	88
Albumen	7
Fatty matter	5

100

For the purpose of making a complete analysis we should cut the brain into thin slices, treat it, several times by boiling alcohol, leaving it in contact with this liquid for some days; then we should express it, rapidly pulverize it, and act on it first by cold, and subsequently by boiling, ether. The pulp left after this treatment is nothing more

than coagulated albumen mixed with the coats of the vessels, &c.

The immediate principles obtained from these solutions, are—1. A peculiar acid body, called cerebrie acid. 2. Cholesterine. 3. A fatty acid, named oleo-phosphoric acid. 4. Traces of oleine, margarine, &c.

Cerebrie Acid.—To obtain this body, we react on the mass resulting from the evaporation of the ether by a fresh quantity of this menstruum; we thus procure a white precipitate, which is to be isolated by decantation, and which, when exposed to the air, quickly becomes transformed into a wax-like, fatty mass. This precipitate contains cerebrie acid combined with soda, oleo-phosphoric acid united with lime or soda, phosphate of lime, and albumen. This must be again taken up by boiling absolute alcohol, slightly acidulated by sulphuric acid. The sulphates, mixed with albumen, remain in suspension, and are to be separated by filtration. The cerebrie and oleo-phosphoric acids become deposited on cooling. Cold ether takes up the oleo-phosphoric acid, whilst the cerebrie acid is to be dissolved in boiling ether, and then allowed to crystallize.

The acid thus obtained is white, forming crystalline grains. It is dissolved in boiling alcohol. Like starch, it possesses the remarkable property of swelling up in water without dissolving. It melts only at a very elevated temperature—so great, indeed, as almost to cause its decomposition. It burns, giving out a characteristic odour, and leaves an acid charcoal difficult to incinerate. Sulphuric acid blackens it; nitric acid decomposes it very slowly.

Dr. R. D. Thomson has given another process for preparing this acid; he separates as much as possible the membranous part of the cerebral mass; cuts the brain into small pieces, and then digests it, by the aid of a gentle heat, in about twenty times its weight of weak potass-ley; by rest, a very slight white precipitate is thrown down; he removes by decantation the limpid liquid, and pours some pure water over the deposit; when the liquid is clear, he again decants it, and boils the precipitate with tartaric acid. The surface of the mixture becomes covered with a white substance, which is to be removed. To extract from it the cerebrie acid, he washes it with boiling water, dries it on a porous tile, exhausts the desiccated mass by ether, and crystallizes the residue in boiling alcohol. This acid contains:—

	Frémy.	R. D. Thomson.
Carbon	66.7	67.01
Hydrogen	10.6	10.85
Nitrogen	2.3	2.21
Phosphorus	0.9	0.16
Oxygen	19.5	19.41

100.0 100.00

Cerebrie acid combines with bases, and forms with them insoluble, or very slightly soluble, combinations. It is a very feeble acid, which, according to M. Frémy, greatly resembles some fatty acids and animal substances, which have the property of combining with bases, as albumen and fibrine.

Oleo-phosphoric Acid.—We have seen that the cerebrie acid is precipitated on adding fresh ether to the product left by the evaporation of the etheral solution; there remains, however, dissolved in the ether, a viscous substance, which contains oleo-phosphoric acid, frequently combined with soda. To purify it, we are to treat the product obtained by an acid, then react on the mass by boiling alcohol, and, on cooling, we shall have deposited impure oleo-phosphoric acid, which is to be freed of oleine and cholesterine, by washing in cold ether and alcohol, in which it is less soluble than are these principles. M. Frémy has not been able to obtain it perfectly pure and free from all cerebrie acid, cholesterine, and cerebral oleine (*cerebroleine*).

Oleo-phosphoric acid is ordinarily of a yellow colour, like oleine; it is insoluble in water, and swells up a little in this fluid when boiling. It has a viscous consistence. When brought into

contact with bases, it combines with them, and constitutes a matter possessing all the properties of the mass which we obtain from brain by means of ether. It burns in the open air, and leaves a very acid charcoal, impregnated with phosphoric acid.

By prolonged ebullition with water or alcohol, it becomes transformed into an oily matter, identical with oleine (*cerebroleine*), and into phosphoric acid; this decomposition is greatly accelerated by the presence of a free acid, and takes place without the intervention of the air. It moreover, occurs in brains which have commenced to putrify.

Oleo-phosphoric acid contains about two per cent. of phosphorus. The bases transform it into oleic acid, phosphoric acid, and glycerine.

M. Frémy analyzed some cerebral oleine, and found in it numbers equivalent to those which M. Chevreul deduced from the analysis of the oleine of human fat. He has, moreover, proved in the brain the presence of oleic and of margarine acids.

Dr. R. D. Thomson extracted from the brain a substance crystallizing in beautiful flat prisms, and which does not resemble cholesterine; he has not obtained it pure; his analyses gave him:—

Carbon	from 81.9 to 81.5
Hydrogen	from 13.5 to 14.0
Oxygen	from 5.8 to 6.5

These numbers differ greatly from those furnished by cholesterine itself.

According to Vauquelin, the spinal marrow and the medulla oblongata offer a very analogous composition to that of the brain; only, they contain more fatty matter, and less albumen, extractive matters, and water.

Sometimes, but rarely, we find concretions in the brain; these are formed of the earthy phosphates, cholesterine, and animal matters. John met with one which contained 75 per cent. of phosphate of lime and magnesia, and 25 per cent. of animal matter. That which was analyzed by M. Morin, was formed of cholesterine, coagulated albumen, and earthy phosphates.

Lassaigne analyzed a cerebral concretion in a horse, which contained

Cholesterine	58.9
Coagulated albumen	39.5
Cellular tissue	2.5
Phosphate of lime	2.5

100.0

Vauquelin further affirms, that the nerves possess a composition similar to that of the brain. They, however, contain a little less solid fat, and rather more liquid fat, than that organ. They swell up in boiling water; and, by bullition in alcohol, we separate from them a liquid fat, which collects at the bottom of the vessel. A solution of caustic potash dissolves their albumen; the fatty matter forms with it an emulsion, and the *neurilemma* alone is left behind.

The *ganglia*, of which the structure is more compact than that of the nerves, contract in boiling water, and it is only by prolonged bullition that we can succeed in softening them. Caustic potash gradually dissolves them, when aided by bullition.

NAVAL APPOINTMENTS.—Surgeons: Pete, Niddrie, M.D., to the Asia; John Gallagher to the Arab.—**Assistant-Surgeons:** Dr. Henry Richardson, to the Spider; Thomas M. Costello, to the Excellent; John H. B. Collins, to the Oberon; H. C. J. Wilson, to the Asia; Richard Butler, to the Arab; James J. Ayerest and William Evans (b), to the San. Josef; John Cotton and Richard B. Power, to the Victory; William Domville, to Greenwich Hospital.

CHOLERA.—The *Admiralty Gazette* of the 9th inst. announces that the cholera had advanced from Kari to Tschilter, and to Olti, eighteen leagues from Erzeroum. It was feared that this scourge would reach Taganrog, in consequence of the frequent communication between the latter port and Erzeroum.

Reported for the MEDICAL TIMES by ALFRED MARK-WICK, Esq., Surgeon to the Western German Dispensary, and formerly Externe to the Venereal Hospital, Paris, &c.

ON STRICTURE OF THE INTESTINE IN HERNIE.—BY DR. LOUIS CHAPEL, OF SAINT MALO.

The subject of this paper is one in the history of hernia to which but little attention has been paid, and of which we possess but few perfect cases. Are we to conclude from this that it is an affection of rare occurrence? The obscurity which existed, even till lately, relative to the seat of the strangulation, and which has now, under the influence of the beautiful and patient investigations of M. Malgaigne become removed, leads one to believe that by more attentive observation we should have been enabled to discover sooner this cause of accidents that have been hitherto but badly explained. The researches I have thought proper to institute have led me to the following results, with which I intend to preface the remarks I have to make on the case about to be recorded:—

In 1765 the question of stricture of the intestine in cases of hernia was considered by the Academy of Surgery, in consequence of a case that was laid before it by Ritsch, in which it was stated, "that the ilion was found as much constricted in two places, in the situations which had been strangulated by the ring, as if it had been forcibly tied with a piece of thread." This case, which Ritsch believed to be without a parallel, called forth similar instances that had been met with by Mertrud and Coutavoz, who, at the *post-mortem*, recognised a stricture at the point where strangulation had taken place.

Heister, in his "Institutions de Chirurgie," mentions that, after the operation for hernia, the patient may be seized with hiccup and vomiting; but he appears not to suspect that these symptoms may depend on stricture of the intestine. I met with no better success in looking through Arnaud or J. L. Petit.

John Hunter, in his "Treatise on Inflammation," states having found the intestinal canal closed by plastic lymph after a strangulated hernia.

Pelletan informs us, in his "Clinique Chirurgicale," that he had an unsuccessful case after an operation for strangulated hernia, owing to a stricture of the intestine.

Astley Cooper, who has varied his observations on hernia so much, does not appear to have given his attention to this point of pathological anatomy now under consideration.

Lobstein makes no mention of stricture of the intestine in his "Traité d'Anatomie Pathologique." Not so, however, with M. Cruveilhier, who alludes, in his "Essai sur l'Anatomie Pathologique," to the stricture and obliteration of the displaced intestine; he even divides the stricture into acute and chronic, and is of opinion that the continued pressure of an imperfect bandage may be the cause of it. (a)

Boyer, in speaking of the accidents that may follow an operation for hernia, says, "that there were no distinct signs to point out whether the continuance of the symptoms was owing to stricture or to strangulation of the intestine; but that it might be presumed to be due to either one or the other, when laxatives and antiphlogistic means were without avail."

"The constriction of the intestine within the ring is a fact admitted by all authors, and has been long since placed beyond a doubt by the case related by Ritsch. In a patient operated on by this surgeon, the symptoms continued after the reduction; on opening the body the cause immediately presented itself; that part of the alimentary canal which had been strangulated was found so con-

stricted as to admit with difficulty an ordinary-sized quill. Other examples of a narrowing of the intestine remaining within the abdomen have since been recorded; I have myself met with some, but their nature appears to me to have been mistaken. There is nothing organic or permanent about them. They may be removed in a few seconds with the fingers, when we have them at command; a purgative generally overcomes them after the operation, and it would be cruelty to stretch the organ beneath in order to enable us to distend them from within outwards before the reduction is effected."—*Velpeau, "Nouveaux Elements de Médecine Opér." 2nd Edit.*

In a memoir on "Enterotomy of the Small Intestines," published by M. Maisonneuve in the "Archives Générales de Médecine," 1845, is contained an enumeration of the causes by which the intestine may be constricted. The author, after having alluded to a forcible constriction being practised on the coats of the intestines, adds that "this latter variety is the most frequent of all. When a loop of intestine has been submitted to the powerful constriction of a hernial ring, it frequently becomes the seat of an organic stricture, which prevents the free circulation of the fecal matter, and which may be divided into primitive and secondary."

The authors of the "Nouveaux Eléments de Pathologie" merely mention the fact in question. "Generally speaking, they say the intestine is contracted in itself, and the course of the feces is only impeded."

Lastly, M. Vidal (de Cassis) states, in the second edition of his "Pathologie Externe," that the displaced intestine sometimes becomes contracted; and he adds in another place, "that part of the intestine which has been constricted undergoes the most severe and rapid alterations. The first effect observed in it is stricture of the part strangulated. This stricture is the more powerful, and continues for a greater length of time after the cause has been removed, the longer the strangulation has lasted."

CASE 10.—A female, aged seventy-four, weakened by age, poverty, and disease, has occupied a bed as an infirm patient for nearly three years, in one of the medical wards of the Hôtel Dieu at Saint Malo. It was impossible to fix the patient's attention on the previous history of her complaint, or to ascertain the disease for which she entered the hospital. None of her relations knew that she had a hernia, and she herself perhaps was ignorant of it, until the 5th of August, 1846, when the surgeon was made aware that she vomited and complained of colic. Futile attempts at reduction were made on a tumour that was discovered on the right side. I saw the patient the following morning, and found her in the following state:—Face very pale, but not sensibly altered; pulse regular and apparently normal, from sixty-six to seventy in a minute; the extremities are cool; there is dyspnoea and frequent vomiting of thick matter resembling feces much diluted with water. Strong pressure on the abdomen causes no pain to the patient. On examining the right inguinal region with my friend and colleague Dr. Behier, we detected a hard tumour, somewhat painful, extending in the direction of the fold in the groin, but rather below it, and about the size of a very large chestnut. I in vain employed the taxis; M. Behier did the same, but with no better success. She was ordered frictions with the extract of belladonna.

We again examined the patient at eleven o'clock. She then replied indifferently to questions; there was some prostration, but neither headache nor thirst; pulse sixty-six to seventy in a minute; skin cool; matter vomited similar to that in the morning; no pain in the abdomen. The taxis was again employed, but without success, and with some pain. She was ordered warm bath, and to remain in it two hours; laxative enema, and frictions with extract belladonna.

I tried, while the patient was in the bath, to reduce the hernia, but not succeeding, I recom-

mended her, although not without some difficulty, to submit to the chances of an operation.

I made an incision on a fold of integument parallel to the length of the tumour, and, by dividing layer by layer the cellular membrane, I reached a tissue which I took for epiploon, but was not so. On opening the sac a small quantity of a reddish-coloured serum made its escape. I passed the finger between the bowel and the sides of the sac, so as to destroy the adhesions that existed, and then directed it towards the external aperture, and endeavoured, by pressing down the intestines, to reach the strangulated part, but was unable to do so. I made tense the sides of the sac, and introduced a director with some difficulty between the intestine and the neck of the sac, on the inside of which I divided the stricture several times, together with Gimbernat's ligament. My finger then penetrated freely into the cavity of the abdomen. I examined the bowel, which I found much injected, and reduced it; the reduction being scarcely effected when a large quantity of serum several times made its escape. The usual dressing was applied.

On visiting the patient two hours after the operation, I found her in the following condition: Pulse regular, from seventy to seventy-four in a minute; countenance more satisfactory; no headache, and she has drunk without vomiting. The abdomen is supple and without pain; she has had no evacuation from the bowels. Two purgative enemata, ordinary tisan.

Passed a restless night on the 7th; the neighbouring patients state she was rather delirious. She has passed water once, and has had one stool. She does not complain of colic. Heat of skin moderate, pulse not frequent. There is neither thirst nor nausea. Continue the ordinary tisan, and a little milk and water granted as the patient desired it.

I was sent for at one o'clock in the afternoon, when I was informed by the nurse that since twelve she had had bilious vomiting, and passed several stools involuntarily. The features are much altered; the pulse is small and frequent, and the skin cold. The abdomen is neither tympanitic nor painful. To take an opiate draught, ice-water to drink, a quarter of a starch glyster to be administered, bottles of hot water to the feet.

At four o'clock I again saw the patient. The vomiting still continued. I examined the wound, but it presented nothing unnatural in appearance. The patient began to shiver as soon as she was uncovered. The limbs have regained their natural temperature; the pulse only seventy-four in a minute, and small. The abdomen is neither painful nor swollen. She continued in this state till midnight, when she expired.

Secutio cadaveris eighteen hours after death, in the presence of Dr. Behier, presented the following appearances:—A very small quantity of serum within the abdomen; the intestinal convolutions slightly injected; recent adhesions to a slight extent on a level with the right Poupert's ligament; some parts of the intestine adhere together, and to the abdominal wall. In the midst of these intestinal loops, which are of a dark red colour, I perceived a spot very strongly contracted, as if that part of the bowel had been submitted to the pressure of a ligature. To the touch it feels like a fibrous ring of not more than twenty-seven or twenty-eight millimètres in circumference; while the portion of intestine above it is as much as ninety-six millimètres, and that below it seventy millimètres. The intestinal mucous membrane in the neighbourhood of the stricture is slightly inflamed; there is, however, no ulceration either on it or on the serous membrane. The remainder of the digestive canal, as also the other viscera, presented nothing worthy of notice. The neck of the sac is thickened.

Such are the simple data which I considered it necessary to furnish in order to elucidate this case, which I consider interesting in more than one point of view. In the first place, let us see whether all authors agree as to the possibility of there existing a permanent obstacle to the pas-

(a) This was also the opinion of Garengeot, who thought that the pressure of a badly-constricted bandage might constrict the intestine.

sage of the fæces. One of our most justly celebrated surgeons, M. Velpeau, expresses himself in terms which no longer leave any doubt in the mind, when he says "that strictures of the intestines have nothing organic or permanent about them. They may be removed in a few seconds with the fingers, when we have them at command." I regret much to place myself in opposition to so distinguished a master as is Professor Velpeau, but the case above quoted is one against which all theories must fall. I do not deny that the transient diminution of the intestine is the most common form; but, as regards the existence of the permanent stricture, I appeal to the true observation of facts, which will not be wanting when the attention of surgeons has been more particularly directed to this point of surgical anatomy. The intestine which I held in my hand, and which my colleague Behier examined as well as myself, was thickened, hard, and fibrous to the extent of a few millimètres, the tractions to which it was submitted not altering in the least its diameter. "A more frequent lesion than the inorganic stricture," says M. Velpeau, in his "Médecine Opératoire," "is ulceration of the external surface of the intestine." Would not M. Velpeau imagine that, when the bowel is reduced, the process of cicatrization may occasion a diminution in the calibre of the intestine, which I conceive ought to be permanent? This is, at least, one way, and I think not an improbable one, and to which I know of no allusion having been made of explaining the cause of permanent strictures.

M. Tessier published an essay in the "Archives Générales de Médecine," for 1838, in which he particularly insisted on the paralysis of the upper end of the intestine, and the necessity of administering purgatives immediately after the operation. "If the obstacle to the passage of the fecal matter," says M. Tessier, "can be mechanically produced by the narrowing of the tunics in the seat of the constriction, and by the swelling of the mucous membrane of the strangulated loop, still these cases are rare."

How was the stricture in this woman produced? Must we, with John Hunter, admit that an effusion of plastic lymph, which has become organized, has taken place as the result of inflammation? or that it has arisen from the continued pressure of an imperfect bandage, as the opinion of Professor Cruveilhier? to the constriction of the ring or of the neck of the sac? It is evident that in the case in question it cannot be attributed to the effect of a bandage, since the patient had never worn one. There remains, therefore, the very probable hypothesis of the ruptured intestine being strictured by the neck of the sac, inflammation and its products being the result. Nothing more was necessary to impede the passage of the fecal matter than a slight degree of inflammatory action to tumefy the mucous membrane, and diminish more or less the calibre of the intestine. What occurred here I have observed, as indeed all other surgeons have done, in certain cases of stricture of the urethra.

The same cause has produced the same results, which are, in both cases the dilatation of the canal behind the obstacle. Repeated coitus, severe mental emotion, a change of temperature, or an excess at table, causes the mucous tissue to swell, and the stream of urine, which was tolerably large, diminishes to such an extent as to cause stranguary and even ischuria. At the *post-mortem*, we shall probably be astonished to find that the stricture is not very extensive; but we must not forget the state of congestion of the parts, and the spasm which may exist in the intestinal canal as well as in that of the urethra, and which disappears during death.

The operator, after having divided the stricture, ought to examine the parts with the greatest attention. It is from not attending to this precept that several surgeons have had the misfortune to lose their patients, without being able to obviate the painful result. He should draw the intestine towards him in order to ascertain whether it has suffered constriction, or is in any way altered. By neglecting to do this,

I had the sad advantage of making a *post-mortem* examination of the body, and an opportunity of studying this question with more attention than I otherwise should have done. In the memoir already quoted, Ritsch makes the following remark:—"I felt how important it was, in every operation of this nature, not to reduce the intestine after dilating the ring in inguinal or complete hernia, and the crural arch in femoral hernia, without previously withdrawing a little the loop of the protruded bowel, for the purpose of examining the nature of the impression that has been made on the part strangulated. If there was a band or an obliteration, which it was evident would prevent the passage of the fæces, I would on no account reduce the intestine, as death would be the inevitable result." Reflection on these sensible observations of Ritsch would, I am persuaded, convince those surgeons who still hesitate to follow his advice of the importance of acting as he has stated in drawing the intestine towards them, at the risk of experiencing more difficulty in the practice, as some imagine.

The utility of purgatives is far from being acknowledged by every one; and although they may be had recourse to by MM. Velpeau, Tessier, &c., they are not by L. J. Sanson, who stated, in 1833, that "formerly it was considered an advantage to promote the alvine evacuations by means of purgatives administered by the mouth or *per anum*, and the practice is still recommended by some persons. But, if we consider that constipation is the result of inflammation, we shall at once perceive that purgatives, although they may occasion evacuations, are, nevertheless, more dangerous than useful, and their employment will be rejected." Consequently Sanson was influenced by physiological medicine, and exaggerated the action of purgatives after an operation for hernia. For my own part, without having so great a repugnance for evacuates, I think it prudent first to have recourse to simple or laxative enemata, and only to employ purgatives when these have failed. Such was the course I pursued with my patient, who certainly would not have been benefited by the most drastic cathartics. The digestive tube, both above and below the stricture, contained only a small quantity of diluted fecal matter, which the patient had not the time, as it were, to get rid of either by vomiting or *per anum*.

The duty of the surgeon, when he has ascertained that the intestine is contracted, and that its parietes are thickened, must frequently be fraught with difficulty. Ought he to expose himself to the very uncertain chance of success, by reducing the bowel, as Dupuytren appears to have done in a similar case? or is he to slit up the intestine above the contracted point, without, however, fixing it at the abdominal opening with La Peyrouie's ligature, which Scarpa considered as useless and even dangerous? The cases related by Louis in his memoir "On the Cure of Hernia," when gangrene has taken place, are such as to induce the surgeon to establish an artificial anus. This celebrated surgeon even proposed to apply this operation to the small intestines, in cases where stricture has been the result of the strangulation. "If I were called," says he, "to attend a person who had been cured of a hernia by gangrene, the pain of which over the cicatrix, together with the vomiting, indicated an obstruction of the canal above the narrowing of the intestine, I should not hesitate to make an incision to procure the evacuation of the fæces, and should maintain a drain through the wound which would henceforth serve the purpose of an anus. This operation, if performed in time, would have saved the lives of many." It appears certain that the method by which an easy flow of the fecal matter through a new anus is procured would secure the patients from subsequent unfavourable occurrences, and diminish the danger.

In a case where there exists a stricture which does not allow the fecal matter to pass, the indication, in the opinion of Ritsch, is no less positive than urgent. "I should not hesitate," he adds, "to cut the loop of intestine above the

stricture so as to remove the whole of it that was comprised within the ring." He then recommends Rambdohr's method, as modified by Sabatier, to be followed, which consists in introducing into the intestine a card varnished with oil of turpentine. We must, therefore, necessarily form an artificial anus, and endeavour to dilate the bowel, or else cut through the intestine, and afterwards bring it together again: M. Jobert's (de Lamballe) proceeding of enterostaphy.

If, in spite of the operator's wish, the intestine returned, or if, unobserved by him, the symptoms continued after the operation, we must then imitate M. Maisonneuve, who decided on seeking the intestine two days after he had operated on a lady, aged sixty-four, whom he was fortunate enough to save by this hazardous determination. —*Revue Médico-Chirurg.*

19, Langham-place.

THE PHYSIOGNOMY OF DISEASES OR SEMEIOTICS IN THEIR ASSIMILATIVE CHARACTERS.

By GEORGE CORFEE (Author of "A Popular Treatise on the Kidney," &c.), of the Middlesex Hospital.

[Illustrated by Portraits of Cases.] (a)

(Continued from p. 571.)

OTTIS.

When inflammation falls upon the internal ear, in consequence of any slow disease which is progressing in the petrous portion of the temporal bone, the symptoms of such a disease are most insidious, deceptive, and fatal. There is no part of the bony structure of man that is so dense as this portion of the skull, and yet there is no part of the osseous system that undergoes such fatal changes *intra scrofulous* constitution as the above-mentioned bone. If a patient complains of lassitude, mental and bodily depression, if he presents a dull and rather hypochondriacal countenance, and if, moreover, he has had a discharge from one ear, and it has suddenly ceased, and he has become deaf, whether he complains or not of any head symptoms, yet these are alone sufficiently serious to awaken alarm in the mind of an attentive and observing practitioner. Let the inexperienced student beware of treating such cases with levity. Sometime since a young gentleman of the legal profession was "out of sorts," as his friend, a relative of mine, expressed it, but not feeling ill enough to send for medical aid. My friend insisted on his having advice, or else going to his chambers. He preferred the former, when an eminent surgeon of the Borough hospitals was called in, but, as his patient made no complaint, he told my friend that he thought he was "hipped," and ought to be roused and be made to go to his professional duties. They tried that advice, but it was all to no purpose, the patient declared he could do nothing but lie upon the sofa and read. Three or four days after this occurrence my friend, who lodged with him, thought he noticed a slight aberration of mind as he was conversing, and, becoming alarmed, he requested the surgeon to call in a physician, which was accordingly done. The latter gentleman made known his suspicions freely to his friend, requesting that he would communicate with the patient's father, stating at the same time that he feared there was slow disease going on in the brain. The next day the gentleman complained of earache, and in twenty-four hours more was furiously delirious, and lingered for a few more hours, when death terminated the scene.

There was arachnitis of one hemisphere of the brain. The petrous portion of the temporal bone was pulpy; the mastoid cells and cavity of the tympanum were filled with purulent matter.

Another instance occurred here, when the un-

(a) These portraits, which are painted from the life, by that eminent artist George Fogg, Esq., are to be seen in the museum of the Middlesex Hospital School of Medicine, a woodcut being deemed inefficient to carry out the peculiar features and tint of each countenance.

usually marked features of the disease could leave no doubt as to the diagnosis. However, by mild forms of mercurial treatment, depletion from the mastoid cells by leeching, &c., he ultimately recovered, and my case-book reports him to have been discharged convalescent from the hospital.

Destruction of the ossicula auditus, and softening of the petrous portion; ulceration of the tympanum, and purulent secretion from the whole mastoid cells, can exist without any other striking symptoms than those already enumerated. This has been repeatedly witnessed, as the following among the many instances will show:—

William Clements, aged twenty-one, painter, was admitted Sept. 29, with the following symptoms:—Somewhat emaciated; countenance pale and thin; features shrunken, expressive of anguish; eyes dull; deaf in the right ear, suffers no pain in it, but there is pain over the frontal and temporal bones of this side; no vertigo or delirium. States that he has had earache accompanied with discharge.

Six weeks ago he got wet through; shivering, followed by fever and pain in the head, supervened. The former ceased, but the headache recurred from time to time ever since. The headache has been intermittent, though not observing any stated periods of recurrence, until six days ago, since which time it has been constant. He says that through life he has been subject to earache on the right side, which has been attended with discharge and relief to the pain. C. c. ad ʒviij. temp. dex. et ol. ricini ʒss. st.

Oct. 2. Pain relieved by the cupping, but through yesterday he lay quiet, occasionally starting up and shrieking out with pain; towards evening on this day he became insensible, and the extremities cold. In the course of an hour he rallied out of this collapse, but remained in a state of stupor, though he was easily roused, and complained of a sense of weight over the right side of the head; drowsy and impatient of being spoken to; pulse 96, hardish. Pil. hydr., gr. v., ter. rep. c. c.

5. Coma more complete; iris of the right eye insensible to light; increased sensibility of that side of the face; no paralysis; slight conjunctivitis. In the course of the following day his breathing became stertorous; insensibility was complete, and he sunk rapidly, and died the same evening.

Autopsy Twelve Hours after Death.—Head.—No notable vascularity of the membranes; no effusion beneath them; firm adhesion of the dura mater to the petrous portion of the right temporal bone, in a small space external to the ridge beneath which are the semicircular canals. It was easily detached from the bone, and was found to be almost cartilaginous in consistence. The bone at this part was rough and partially destroyed; the brain, opposite this adherent portion of membrane, was soft and pulpy to the extent of two inches. An incision was made into this softened substance, when an ounce of greenish pus flowed out. This matter was contained in the distinct cells, of which the parietes were complete, formed of a hardened mass of cerebral substance, and possessing a red, vascular, and flocculent internal lining. Beyond these hard margins the medullary matter was of a dusky yellow colour, and very pulpy. The largest of the three abscesses extended to the base of the lateral ventricle over its posterior horn. These latter cavities were full of clear serum. On carefully examining the internal ear a small abscess was found just above the mastoid cells which communicated with the tympanum, and had destroyed the small bones and membrana tympani. There was no communication whatever between this abscess and the cavity of the cranium.

Malignant disease of the brain, or tumours within the cranium, give rise to a train of symptoms which are strongly assimilated to those organic lesions that have been already enumerated. However opposite these morbid changes may be, and however they may differ as to their origin

and their progress, yet the attentive physiognomist cannot fail to discern a remarkable assimilation of features in the broad outline of them all. It requires a practised eye to discriminate these likenesses, but with the exercise of some tact and judgment they soon become capable of distinction, and the tutored mind seizes on their varieties, but general resemblance, before it allows the statements and complaints of the patient to carry it away to an indistinct combination of less intelligible proofs.

In cerebral diseases, beyond all others, the physiognomy is most instructive. The student in this valuable branch of medical study should accustom himself to search, fix, and class some of the external signs of internal diseases, as portrayed in the face, as in the brow, forehead, the eyelids, the cheeks, the nostrils, the lips, and, above all, the expression of that index of the mind, the eye.

The following instance of fungus medullaris of the brain will elucidate some of the foregoing observations:—The facial paralysis did not depend upon simple thickening or inflammation of the neuroma of the nerves of expression and motion, as is the case in ordinary instances of twisted face, but other grave and more serious features were recognisable in the countenance, which clearly denoted destructive mischief in the substance of the brain itself.

Samuel Dovey, fifty-seven, tailor, admitted Feb. 26. A tall, athletic man. Drags his left leg after him; left arm in a state of semiflexion, and powerless; countenance singularly distorted from paralysis of those parts supplied by the portio dura on the left side; deaf in the right ear; pupils natural, but does not see distinctly with either eye; overhanging eyebrows; general aspect of the countenance dull and distressed. Acknowledges that he has pain over the right eye, which comes on worse in the evening, and affects the whole head, so that he is obliged to hold it with both hands in order to obtain some relief; the deafness, he thinks, came on from the severity of the pain. Ten days ago he found out the paralysis of the face by not being able to spit; he never had a fit, but says his memory is not so good as formerly. The hemiplegic symptoms are of a few days duration only.

℞. Hydr. chlor., ij.; opii ʒ bis. die; c. c. ad ʒviij. nuchæ. Emp. canth. ponē aures.

From his admission to his death, the following notice was made of his heart's action:—"Impulse increased; the systole attended with a sharp noise, like the sound produced by passing the finger briskly down silk or bombazine, most evident at the base of the heart; respiratory murmur healthy."

From this period to his death, which took place on the 29th March, he had several fits of coma and convulsions, for which he was bled to 10 oz., and on another occasion the c. c. was repeated. The last fit occurred on the 16th, when he was found breathing stertorously, lips flapping to and fro in each respiration; face flushed and turgid; head hot; paralysis unaltered; gums sore; perfect insensibility; evacuations pass involuntarily; sloughing of the nates; heart beating forcibly; temporal arteries distended and firm; one of the latter was opened, and ʒxvj. of blood removed, which reduced the power of the pulse and turgidity of the countenance, but did not alter the other symptoms. He roused somewhat in the course of the following day, but again became drowsy, and gradually sunk; the nates had sloughed to a great extent.

Autopsy Twelve Hours after Death.—Chest.—No fluid in the pleura; serum, tinged with blood, resembling porter, in the pericardium; heart large and loaded with fat; a deposit, more like fat, on the tricuspid valve; left ventricle hypertrophied; mitral and semilunar valves irregularly thickened. Many atheromatous deposits along the aorta, with puckering of the membrane. Just within the ventricle, and half an inch from the commencement of the aorta, the inner membrane was white, opaque, and along the middle of this space, parallel with the circumference of the aorta, and in the same line with the attachment

of the mitral valve, ran a prominent line or ridge, whiter than any other part, and having the feel of a sharp cord. On closing the ventricle, it was manifest that at this part of the chamber a real stricture had been constituted. (a) Head.—Sulci between the convolutions dry and flat, and not very apparent. Substance of the brain firm, and marked by several red puncta. Left lateral ventricle enormously distended with clear serum, and of great size even when emptied; on the other side the walls of the ventricle were forced nearly into apposition by the pressure of a tumour, which occupied a large portion of the right hemisphere, the central part of the tumour being rather posterior to the centre of the hemisphere. The posterior portion of the tumour was of a red colour, and soft; centrally it had a light orange tint, and a spongy cellular structure; the anterior part was hard, homogeneous, and pearly in appearance. The tumour was about three inches in length and nearly two in breadth, and of considerable thickness. In a subsequent section an apoplectic clot, as big as a hazel-nut, was found at the under part of this growth. (b) The plexus choroides was hard, irregular, and enlarged at its posterior part or extremity. The arteries at the base were covered in several parts with white calcareous deposits, and they were dilated at this spot. The portio dura and mollis, where they emerge on the right side as distinct chords, were as if adherent to each other, and the former nerve was both larger and harder than its opposite. So also it was found where it entered the petrous portion of the temporal bone. A projecting nipple-like portion of the brain existed immediately above the point of emergence of the seventh pair of nerves, and apparently had caused pressure on that part. The portio mollis was softened and nearly invisible at the first glance. This projection arose, seemingly only, from a part of the brain that was pushed over by the tumour. The sixth nerve on the diseased side was larger than the opposite one.

In the instance of a young female, of strumous diathesis, and who laboured under symptoms of cerebral disease, precisely analogous to the foregoing case, perfect recovery followed the inunction of the tartar emetic ointment on the shaved scalp, over the surface of the seat of the disease. The patient was rapidly sinking, with loss of consciousness, hemiplegia, deafness, involuntary action of the sphincters, when our late and intelligent house-surgeon, Mr. R. Pyper, now in the 11th Hussars, visited the ward, and suggested the immediate and persevering use of the above remedy, and the result in the course of one week was most gratifying and decisive. She left the hospital convalescent, and returned six months afterwards to pay a visit to the day nurse of the ward, who remarked that she looked quite well, only that she thought she was "rather silly."

ANEURISM OF THE INTERNAL CAROTID ARTERY. PARALYSIS ON THE DISEASED SIDE OF THE BODY.

David Pedhurst, gilder, aged thirty-five, May 19. Countenance pale and heavy; deafness; constant drowsiness during the day; pulse 70, with power; tongue furred, but moist. Complaints of great pain in the head, particularly at the left side; and shooting down the spine. Bowels torpid.

Ill four months with pain in head and occasional giddiness, and dreaming at night. Eight days ago was walking in the street, when a sudden dimness of vision seized him, and he fell insensible; after a short time his senses returned, but he observed a partial loss of use

(a) Could this give rise to the peculiar sound of the ventricular action? or did this abnormal sound arise from any altered action of the mitral valve, with the insertion of which the line of stricture was continuous?

(b) It is a matter of question whether this was the result of the destruction of some small vessel in the progress of the disease, and whether it occurred on the 16th ultimo, when the symptoms became so suddenly aggravated.

in the left side: the use has gradually returned. The deafness, which he has had from a child, has increased during and since the attack; he has had a discharge from both ears for many years, but it has stopped within the last week. II. gent. c. sen. ter. p. calom. gr. ij. h. et m.

June 1. Frequent vomiting and sinking during yesterday. Has been in a comatose state for the last two or three days; deafness increased; evacuations passed involuntarily. Died in the course of this night without apparent pain.

Examination Twelve Hours after Death.—Brain.

—Its membranes and external surface were very dry—the latter smooth, with the convolutions flattened; there was no excess of vascularity. The substance was exceedingly firm, so as not to be torn asunder; at the front part of the longitudinal fissure the hemispheres adhered one to the other, just above the corpus callosum; the medullary matter was here softer than elsewhere; lateral ventricles distended with bloody serum; both communicated; choroid plexus was pale; upon the floor of the left lateral ventricle were small coagula of blood; and the left corpus striatum was quite soft and pulpy. An incision through this passed to the centre of a large coagulum; the brain around it was yellow and soft; on removing the blood, an aneurismal sack, of the size of a hazel-nut, was discovered at the internal carotid, just after it passed through the carotid canal; it subsequently proved to be just at the commencement of the middle cerebral artery; the porous portion of the temporal bone, just over the tympanum, was softened; the internal surface of the tympanum rough, and denuded of its periosteum; and membrana tympani gone; kidneys each had several small cysts filled with a yellow, thick, gelatinous fluid; enlargement and calcareous deposits in the mesenteric glands; other organs healthy. A small portion of the ilium was given off from the continuous intestine, and inserted at the front part of the pelvis, between the bladder and rectum.

It appears from his history that, about the time of the sudden increase of his pre-existing symptoms, the discharge from the ears stopped, and did not again recur, whence it is probable that this discharge was a salutary effort of nature to ward off a more fatal disease, or at any rate to protract its fatal termination.

It is surprising the extent to which the brain may be the seat of progressing disease on the one hand, or of injuries from cause external to it on the other, without any alteration in the faculties of the mind. During the last twenty hours that I write, a man has been brought here having compound fracture of the skull from a blow by a poker; he was trephined by Mr. Arnott, but has been, and still is, perfectly rational, calm, and anxiously inquiring when he may leave the hospital to get on with a job he has in hand; whilst the following instance of aneurism of the basilar artery, and consequent pressure on the most vital portions of the brain, the pons varolii, and medulla oblongata, tend to show that the symptoms of injuries of the skull and brain are by no means commensurate with the extent of those injuries. (a) The stomach may fill with blood

(a) As a farther proof of this remark it may be added, that the servant of the Duke of Portland was brought here, having just previously been thrown by a spirited horse, and was kicked by the animal in his fall. The whole parietal bone was carried away; the brain was extensively bruised, and lying about the hair, &c.; indeed, this side of the skull was a frightful mass of confusion, laceration, and fracture. The man, nevertheless, was perfectly sensible, and insisted on going to the water-closet from the ward, alone, and was very dissatisfied that he should be confined to his bed. However, this rationality did not last more than two days, when coma, and ultimately death, ensued.

On the other hand, there was an instance of a boy who quarrelled with a strange lad whilst playing at cricket, when the latter seized the wicket and struck the boy, it was supposed, on

before vomiting and syncope ensue; the uterus, too, will often contain pints of blood before contraction of the organ takes place to expel its contents; so like the brain appears to be capable of bearing with the existence of a tumour, or with severe injury, for a longer or shorter period before it manifests any decided train of symptoms indicative of the lesion.

J. Pettiwether, apparently forty years of age, was brought into the hospital at eleven A.M., July 16. He is a short, thick-necked, gross man weighing, perhaps, sixteen stone. Lies perfectly senseless, and was so found in the street half an hour before. He had been working during the week, and was in the enjoyment of tolerable health—that is to say, he made no complaint of sickness. Countenance bloated; eyes closed; pupils contracted; breathing laboured; no apparent paralysis; pulse full and hard. He was bled to twenty ounces, and cupped to the same amount on the nape of the neck, but he rapidly sunk, and died in seven hours, unable to swallow any liquid. On examining the brain it was found gorged with blood, and its ventricles with clear serum. There was no rupture of a bloodvessel, nor extravasation of blood in any part; but the pons varolii, and a portion of the medulla oblongata, were hidden from view by a tumour the size of an ordinary walnut, which proved to be an aneurismal pouch of the basilar artery, full of semi-coagulated blood. The heart was flabby and large, thin in its walls, but dilated in its cavities.

In concluding the subject of cerebral diseases, it may be mentioned that the assimilation of features of some of those derangements which are included in the second division of this first class are so strong that it will be necessary to pass from the one to the other without any further remarks. Injuries of the head, accompanied with intoxication, narcotic poisoning, coma from a sudden invasion of urea upon the nervous system, sanguineous apoplexy, and hysteria, are so allied to each other in some of the broad outlines of physiognomy that it is important to keep the mind closely bent upon these diseases respectively, and yet, at the same time, to attempt to point out wherein the main distinction between them exists.

However, I shall have occasion to advert to this interesting field of pathology when the subject of disorders of the stomach influencing the nervous system is alluded to; and, meanwhile, I would pass on to the consideration of cerebral asphyxia produced by the presence of narcotic poisons, and the circulation of urea in the blood in patients afflicted with degeneration of the kidneys.

Before I proceed to the consideration of the other diseases which are placed in the first division of this class, it may be of great practical utility just to take a retrospective glance of the foregoing cases, and point out the physiological character of each, so that the assimilation of features may be traced in the respective diseases now under notice.

It is often observed that a practitioner may arrive at a correct diagnosis of some obscure disease by first ascertaining what the malady in question really is, and by this means, the mind is led on to an acquaintance with what the actual disease really is. Now, in the preceding group of four cases of cerebral lesion, we may notice the following prominent characters.

In the first, there is complete insensibility, closed eyes, contracted pupils, and a slow pulse. May these not arise from intoxication? The pulse will not allow us to draw this conclusion. May it not proceed from narcotism by opium? This

the head, as the child fell senseless on the ground. On examination we could not discover the slightest bruise, discoloration, or abrasion on the face or shaven head. Insensibility continued, and the lad died in eighteen or twenty hours. The examination of the body did not afford the slightest help in forming an opinion as to the cause of death; since the post-mortem appearances were wholly of a negative character.

is possible, but the unaltered state of the symptoms after the exhibition of the stomach-pump, precludes us from drawing this inference. What other conclusion can we, then, come to, from the above symptoms? I am acquainted with no other means which are capable of producing the above features to a disease, but poison by urea, and sanguineous effusion into the central portions of the brain, thereby causing pressure upon both thalami. The circumstantial evidence tended to form in our minds the latter diagnosis.

In the second, insensibility is not quite perfect, but the eyes are closed; there is no distortion of the features, but there is hemiplegia, and unequal irides. Sudden effusion into one cerebral hemisphere must, therefore, be the cause of these aggregated symptoms.

In the third, the eyes are staring and vacant, and the brows are knitted, which is a strong presumptive evidence that the cerebral disease is not recent, nor from any sudden lesion of this organ, otherwise the lids, as in the former two, would be closed over the eyes.

In the fourth, somewhat similar observations might be made, as on the third case, comparing them both with the two former ones. In fact, we might lay down the following axiom in the study of pathological physiognomy, that whenever a sudden lesion has been offered to the brain, the eyes are closed, and the patient is insensible; whereas, if the same organ is the seat of a slow yet progressive disease, the eyes are half closed, or wide open, and there is some distortion of the features, irregularity in the pupils, and dulness in the whole countenance, with palsy of the body.

Complete insensibility does not follow the presence of effused blood into the walls of one lateral ventricle, for the second patient could answer to our interrogations, but she was hemiplegic; recovery was partially established; and, therefore, we may infer, that where the symptoms enable us to form a correct diagnosis as to the immediate seat of the effusion, we can, at the same time, give some opinion as to the probable results of the case.

But the third instance differs widely from the two former ones. The countenance denoted that a slow, wasting disease had already made severe ravages upon the constitution. There was some power of expressing his feelings still residing in the muscles of the face—he knitted his brows, and his features were pinched. The conjunctivitis, hemiplegia, and, above all, the unequivocal evidences, which we obtained by auscultation, of tubercular deposition in the upper lobes of both lungs, left no doubt upon the mind that the brain was the seat of a disease similar in its character to the one which was making its slow devastations in the chest, namely, tubercular deposition and softening. The greenish serum, it is asserted, is another test of the presence of tubercles in the system.

If we review the fourth case, one of simple ramollissement, accompanied with ruptured aorta, we observe that the cerebral symptoms had been creeping on, in an aged woman, for some weeks before loss of consciousness ensued. The occipital pain, the numbness of the arm and leg, the impaired deglutition, the contraction in the right iris, but, especially, the influence which this slow disorder was capable of producing on the features of the face, would lead the observant and discriminating physiognomist to conjecture the disease which terminated her life. The altered condition of the rhythm of the heart greatly tended to favour the opinion that the cerebral disease was ramollissement consequent upon impaired nutrition and diseased bloodvessels; and the difficulty in deglutition led the mind to suspect that this morbid process was going on at the base, and not on the superficies, of the brain.

It is understood that a commission to inquire into the special means requisite for the sanitary improvement of the metropolis is about to be issued, consisting of Lord R. Grosvenor, Mr. Chadwick, Dr. S. Smith, Professor Owen, F.R.S., and Mr. L. Jones.

SOME REMARKS ON THE EPIDEMICS OF 1846;

and the Influence of Locality in Modifying Disease.

By JOHN GORDON BAILEY,
Member of the Royal College of Surgeons of England.

At the present time, when England and its unhappy sister island are visited by a bad form of fever, it may not be uninteresting to the readers of the *Medical Times* to bring before their notice the following observations on the influence which locality exercises over disease, showing that the type of an epidemic may be changed in many of its features according to the place in which it appears. I am led to do this in consequence of the epidemic fever of 1846 having visited most parts of England, and assumed in many of the towns a character common to all in the commencement, but differing widely as the disease progressed.

I do not profess to bring forward any original views on the nature of a malady about which so much has been written, and such diversity of opinion still prevails, but merely to record my experience of the disease as I witnessed it; and in doing so, I follow the suggestion of Mr. Sibson, of Nottingham, who published a very interesting paper in the *Medical Gazette* of January, 1847, and concluded by expressing a hope that other members of the profession would follow his example: an appeal which has been responded to by many through the pages of the *Medical Times* and other journals.

ENGLISH CHOLERA.

In the month of June, 1846, the small town of Strood, in Kent, which is separated from the city of Rochester by the river Medway, was visited by the ordinary English cholera, which prevails about that period of the year. It differed little from its usual character, except the way in which it was produced. The cause of its appearance at this particular season is generally believed to be owing to the use of unripe fruit, and vegetables; but the year 1846 formed an exception to this rule, for many were attacked who indulged in neither, and those who from peculiar circumstances could not enjoy them had no immunity from the disease.

Now, to what cause was the epidemic to be attributed at this early period? It was the intense heat of the weather. It will be in the recollection of all how warm the months of May and June were, indeed the valuable tables of the Register-General prove that the three months ending with June exhibited at Greenwich a mean temperature of above the average of twenty-five years, and 3° above the average of the corresponding quarter of 1845. This very satisfactorily proves how great an influence heat has in producing the disease, and how it may be the true and only exciting cause, every other being absent; and I arrive at this conclusion from having witnessed its occurrence in infants at the breast, among whom it was very fatal; indeed I met more than half a dozen cases, all of which proved fatal in consequence of the profuse purging being suffered to go on unchecked, which soon brought them into a state resembling that of patients suffering from hydrocephaloid disease, which Dr. Marshall Hall says has its origin in early infancy chiefly in diarrhoea or catharris. I had no opportunity of seeing them before they were brought in this state, persons in the country generally trying a round of their own remedies before seeking medical advice. It is hardly necessary to state that few recovered out of this stage, and those that did had cordial stimulants administered very freely. In one instance only did I know it to terminate fatally in adults, and this was in the case of a delicate young woman of strumous diathesis, who had been confined about three weeks previously, and had been troubled with diarrhoea for some time. In this case the disease set in with all the true characters of Asiatic cholera, and went on through its different stages till the unhappy sufferer was released by death, about twenty-six hours from the commencement of the attack.

FEVER.

As the season advanced, this affection of the bowels began to decline, but was quickly followed by fever. In several cases the disease was ushered in by a copious bilious diarrhoea, but they were more amenable to treatment than those which did not commence for some time after the diarrhoea had ceased. The febrile symptoms were in the commencement well marked: there was the hot skin, quick pulse, furred tongue, headache, thirst, &c. &c.; these were present in each case at the commencement, and persisted till a period varying from the tenth to the fifteenth day, when the disease, from being of the continued type, changed to the remittent; this, with one or two exceptions which I will relate presently, occurred in the great majority of the cases I attended. A shivering fit of great intensity, occurring in the morning or evening, always indicated the change that was about taking place; and this led to a corresponding alteration in the treatment, which was attended with success.

The first case that assumed this character was that of a fine young man who, in the discharge of his duties as a sailor, got wet feet, and soon after was obliged to put himself under treatment, in consequence of the feverish symptoms which appeared. His, like all the others, commenced in the way which ordinary fever does. There was, however, a complication in his case from the beginning, namely, congestion of the liver and pneumonia. The antiphlogistic treatment necessary to get these under reduced his strength considerably, and as soon as it began to fail, rigors set in, followed by great heat and profuse perspiration: the latter, indeed, was most distressing to him, and from his being a fine able young fellow he was soon reduced almost to a shadow. The remedy which proved so serviceable in other cases (quinine) seemed to have little power in checking the disease in him: typhoid symptoms supervened, and after an illness of three weeks he sunk.

The next fatal case was that of a young girl, about twelve years of age, whose illness commenced as simple fever. She was not exposed to contagion, but was one among several of her family in whom the disease suddenly sprung up; with them, as with her, there were all the symptoms of pyrexia present; but a few days after its commencement, rigors set in, followed by heat and perspiration. From this time the character of the disease changed: the perspiration continued, and alternated in her with diarrhoea. An acute attack of bronchitis rendered it necessary to use tartar emetic; and, small as was the quantity which sufficed to relieve the disease, that relief was purchased dearly by the loss of strength which followed: this poor girl lay in a wretched state of exhaustion, for what with complete loss of sleep, diarrhoea, and profuse perspirations, she was terribly reduced. Here was one of those cases in whom some of the features of the Nottingham fever were present, as described by Mr. Sibson: she lay "coiled up, almost night and day uttering a piteous cry," which latter continued till she died.

Another case occurred in the same locality, having also this distressing cry, but it did not terminate fatally: this indicated exhaustion, from which she had nearly sunk. About the same time I was in attendance, with my able and valued friend Dr. Brown, on a young lady whose illness was ushered in by smart fever. The symptoms did not differ from the others in the commencement, but about the tenth day, a severe fit of shivering set in, followed by great heat and perspirations; the latter being established continued for several days; to this was added a most severe attack of bronchitis, and hemorrhage from the bowels. These serious complications made the issue of the case very doubtful, seeing that opposite treatment was required for one, which the others would not well bear; however, it pleased Providence to bless the remedies that were adopted, and she recovered.

LOCALITY.

I may now make a few observations on the

locality as well as on the treatment of the disease.

As regards the locality, it may be said, "as in one district, Strood is concerned, so in another, I witnessed the disease." The town of Strood is situated on a marsh, and this marsh is a fertile source of the malaria, which makes ague always endemic there. This exercises such influence over the constitution that few diseases make their appearance that are not modified by it—all having a tendency to intermit. During the great heat of last year, I attended several women in their confinement, who were attacked with ague during the first week. Now, the majority of the patients I attended lived in Strood and its neighbourhood; their illness commenced in the same way as in other towns, as ordinary fever; but the moment that malaria gained its influence over their constitutions, the antagonism which existed in health was lost, and those suffering under any illness were easily susceptible of its operation. Out of a large number of cases there were but two deaths, and in those most serious complications existed.

TREATMENT.

The treatment in the commencement was simple. The bowels were freely opened if no diarrhoea was present; the body was sponged with tepid vinegar, and water when the temperature was high; and the action of the skin was also promoted by diaphoretics. If complications arose, they were met by appropriate treatment; and the most frequent form was bronchial inflammation; when this occurred after the fever had changed its type, there was much care required in the administration of remedies: those which were found useful were a combination of mercury with chalk, and small doses of tartar emetic, with free counter-irritation over the lungs by means of mustard poultices and turpentine embrocations. When hemorrhage occurred from the bowels, alum in large doses was found very useful, together with opiate injections, and supporting the constitution with quinine, wine, beef-tea, and jellies. This was the treatment that most generally succeeded; and I may observe, the most powerful and, at the same time, most valuable and indispensable remedy was quinine: it checked the periodic rigors, and exerted great influence over the perspirations, which were more amenable to it than anything else that was tried.

Turning from Strood to Rochester, I will briefly relate the heads of two cases which I attended there, and which serve to illustrate the point, that the locality in which a disease appears exercises a remarkable control over the course it takes. This was very manifest in the case of a young girl living in Troytown, a portion of Rochester which is considerably elevated, and removed some distance from both river and marsh: she was the second in the family who was attacked, and had as bad a form of typhus as ever I witnessed. It was not a little interesting to me at the time to meet with a disease which assumed different forms in each town, and I was induced to examine closely into the *fons et origo mali*, believing that a fever so bad, and differing so widely from the comparatively mild form then raging in Strood, should have some very strong cause close at hand for its production. I examined the house, and most clearly traced the cause of this fever to an open privy which was situated at the back of the house, quite exposed to the action of the sun, and producing a most abominable stench. This was not the only case in that locality; I met several which I could safely affirm were caused by the filth which surrounded their houses; in all those cases the distinct type was typhus; there was no sweating or rigors, or any marked remission in the symptoms: the disease ran its course, terminating, however, but fatally in two cases.

Dr. Christison, of Edinburgh, has made some remarks on the local origin of fever, in "The Monthly Journal" for July, 1846, where a similar cause produced the disease. He says—"The origin of the disease from general epidemic

cause was rendered manifestly by the difference of the disease, both in its symptoms and mode of propagation, from the ordinary typhus; there remained, therefore, but one plausible supposition, namely, the existence of a local source of effluvia. This supposition was verified by an examination of the drains belonging to the house and farmyard, which were found to be choked with the ordure from three privies, as well as by the drainage from stables and pigsties, and which, upon being opened, gave rise to the most fetid effluvia, the stench of which was perceptible for a considerable distance."

That fever presents itself in a different type each year is a well-ascertained fact, and is founded on the observation of the most learned physicians since the days of Sydenham, who confessed that he generally lost a few patients at the commencement of an epidemic, till he understood its leading features; indeed, the fever of 1846 was remarkable for its various character: in one place it was simple idiopathic, in another it was remittent, and in a third, typhoid; but in each place that it appeared, its course and character were shaped by the causes that produced it, which clearly proves that locality modifies disease, no matter how it commences. The large towns, such as Manchester, Leeds, and Liverpool, have been severely visited by typhoid fever, and those parts where the disease proved fatal abounded in filth; indeed, there were few of the causes which generally produce fever—such as want of food, irregular habits, in a word, poverty with all its attendants—wanting to generate the disease. In Ireland the same rule obtained, both last and in the present year.

There are few subjects more worthy of the attentive consideration of the profession than those which relate to the sanitary condition of towns; and it is only to be regretted that a Government so wise and powerful as that which presides over such an important portion of the globe should be so apathetic to what concerns the happiness and prosperity of its inhabitants. If the labouring classes in large cities are to reside in houses surrounded by cesspools, breathing the deadly poison of overfed graveyards and badly-constructed drains, how is it possible that health, so essential to labour and industry, can be enjoyed? Let us trust that another session of Parliament will not pass over without the bill so ably constructed by Lord Morpeth (but which had one great omission, in not including the great metropolis along with the large towns of England in its provisions) becoming law. The subject has been often and ably brought before the notice of the profession by the *Medical Times*, whose powerful advocacy it is to be hoped will be continued till the object is attained.

CASES OCCURRING IN THE PRACTICE OF S. P. AITKEN, ESQ.

INJURY OF THE HEAD.

I.—N. Reed, aged ten years, received an injury of the head on the 29th of July last, being accidentally struck by a shovel thrown from a man's hand at the moment of his leaving his work. He walked to the surgery, a distance of about half a mile. On examination a wound about two inches in length was discovered over the most prominent part of the parietal bone, completely dividing the integuments, and disclosing a fracture of the skull extending in a longitudinal direction for more than two inches, the fissure being more than a line in breadth. Further examination showed that a portion of the skull had been completely separated and driven in by the shovel, and was lying loose on the dura mater. There had been considerable hemorrhage.

Treatment.

The wound was enlarged in the antero-posterior direction, and an incision from within outwards made to meet it at right angles. On dissecting back the flap thus formed, another fissure was detected lying parallel with the first, but nearer the middle line of the head, partly sepa-

rating a portion of the skull about two inches long, and half an inch broad. This was removed with the elevator, and showed the dura mater nearly cut through at one part, and the brain pulsating laboriously from the pressure of the detached fragment; this was removed with some little difficulty by the aid of a hook and forceps, and found to be about an inch and a half long, and more than three lines in width at its broadest part, the inner table having given way much more extensively than the upper one, and, on removing it, the brain seemed to recover its healthy action. A single suture was made use of to keep the parts in *situ*, and the wound covered with a dossil of lint. Ordered to be kept in bed, and to take calomel gr. v. at night.

July 30. He slept tolerably, and complains of no pain. Tongue a little white; pulse natural; bowels open.

31. Ordered to poultice the wound.

Aug. 7. Allowed to get up, and have a more nourishing diet. Wound nearly healed.

10. Came up to the surgery. Wound healed. To discontinue the poultice, no bad symptoms having arisen during the cure, and only the one dose of calomel administered in the way of medicine.

I may here observe that in this mining district, where injuries of the head are so common, that in all such injuries the knife is freely used, both to enlarge the original wound, when that is too small to admit of a thorough examination of the state of the cranium, and to divide the fasciæ and pericranium, when that has not been effected in the first instance by the stone or other hard body causing the injury. The trephine is also unhesitatingly employed at once when there is any depression, without waiting for urgent symptoms to come on. And this practice is proved to be the best by the experience of many years and a vast number of cases.

II.—E. Daw, aged 29, miner, received an injury of the perineum in the month of December, 1845, by falling across a tram-iron. About two hours after the accident he attempted in vain to make water, but felt a burning heat in the perineum, and was sensible that swelling had taken place there. About six hours after the accident a catheter was introduced with some difficulty, and about eight ounces of bloody urine were drawn off. Leeches were applied on two occasions to the perineum, and fomentations; but on the fifth day, fluctuation being detected, an opening was made which gave exit to some very offensive matter. A catheter was then introduced and retained for five days, the urine appearing to find its way entirely by it, none coming by the perineum; it was then removed, but introduced night and morning for the next five weeks, at the expiration of which time, on his first attempts to pass his water by the natural efforts, he found it come both by the perineum and the meatus, and continue to do so for about three months, when the wound healed up.

June, 1846. Returned to his employment as a miner.

September. Again laid up with abscess and fistula in the perineum.

Dec. 18. Was admitted into the Truro Royal Infirmary, where a catheter was passed, and retained for two days.

22. Catheter again introduced, and retained for twenty-four hours.

Jan. 1, 1847. Discharged, with the fistula healed.

Feb. 1. Saw the case for the first time. The stricture is a long gristly one, situated about the membranous portion of the urethra, with considerable hardness and thickening of the parts in the perineum. Two fistulæ exist, through which urine and a thin purulent fluid are discharged. The patient is obliged to rise two or three times in the night to make water, which comes away almost *guttatim* after much straining, and cannot retain it for much more than an hour at a time during the day.

Treatment.

A catheter, No. 6 of a set ranging from Nos. 1 to 7, was introduced. After entering

stricture it required steady, long-continued pressure with a light hand to pass it through. It was retained for twenty-four hours, and, not having caused any great irritation, was withdrawn and replaced by No. 6, which now passed very smoothly, and was retained for twelve hours.

Feb. 6. Fistulæ healed. No. 6 passed and retained for a quarter of an hour, and repeated on the 10th and 14th, when it was retained for twenty-four hours, and then withdrawn and replaced by No. 7, retained for a short time and repeated on the 19th and 23rd, and on March 1, 5, 9, 13, 17, and 24, when it was retained for sixteen hours, producing great irritation.

March 29. He now passes his urine in a fair stream, can retain it all night, and for three or four hours at a time during the day. Catheter No. 7 was passed at intervals of four days up to the 13th of May, but without any further improvement. A gristly stricture of an inch long being to be felt in the perineum, the instrument, on arriving at its seat, requires to be held against it with a steady pressure for some time; can then be felt to enter it, and slowly to traverse it. Mercurial ointment was perseveringly rubbed into the perineum for about a month, but without dissipating the hardness.

May 13. He returned to his employment, which he has been enabled to follow up to the present time. I have seen him within these few days, when he expressed his conviction that he is perfectly cured, and his gratitude for the relief afforded him.

From the opportunity I enjoyed of watching Mr. Liston's practice at the University College Hospital for three years, during six months of which I was resident house-surgeon there, I feel convinced that the silver catheter, with a somewhat conical point, is the safest and most efficient instrument for the treatment of these cases.

DR. HEBERDEN'S TREATMENT OF DYSENTERY.

[To the Editor of the Medical Times.]

SIR,—At this period of the year, when dysentery is usually more or less prevalent, I am desirous of calling the attention of the profession to the method of treatment recommended long ago by the celebrated Dr. Heberden. In his elegant commentaries on the nature and cure of diseases the following passage occurs:—

"*Cogitanti itaque mihi de natura dysentericæ, visus est contineri in humoribus vitiosis inclinatis in intestina, quæ inde vehementer perturbata sunt, et in motu inordinatos conjuncta, sic ut intus lædendæ exitum non habeant. Cum vero nullum medicamentum alvum promptius solvat quam sales purgantes (quorum præcipuus est magnesia vitriolata) cum quoque facultatem habeant aliquam componendi motus intestinorum perturbatos, tum rarissimo nauseam et vomitum moveant, sperabam fore, ut non contemnendam opem præberant. Primum itaque dedi magnesiæ vitriolatæ drachmam sextâ quaque hora; quæ brevi levabat dolores, etiam priusquam alvus purgata est. Aliis majorem modum imperavi ex quo non solum fructus præsens perceptus est, verum defectionibus copiosis excitatis, ipsa morbi transierit æger quanquam in tuto ait, tamen vexari solet molesta desidendi cupiditate, propter levem dolorem qui in vecto intestino manet. Huic optime medetur jusculi ovilli pinguis selibra, cui instillatæ sunt tincturæ opii guttæ viginti in alvum infusa; atque hæc sola occasione censeo opium in hoc morbo tuto et utiliter dari posse. In principio certe, ventre noudum purgato maxime noceret. Singultus accepit et aqua fœtida dejecta est ubi dysenteria morte finita est."*

It is to urge the use of this mode of treatment in dysentery that I pen this brief note. I have been in the habit of giving saline purgatives, in accordance with the recommendation of Dr. Heberden, for the last seven or eight years; and I can safely affirm, without a single un-

ACADEMY OF SCIENCES.

Meeting of Sept. 6; M. BROGNIART in the Chair.

ANATOMY OF THE EYE.—M. PAPPENHEIM forwarded a short communication on this subject. His observations had led him to conclude that the conjunctiva of the eyelids still preserved the same constitution as the skin, i.e., the dermis, papilla, the rete mucosum, and the horizontal layers of the epidermis. The papilla disappeared at the edge of the tarsal cartilage; and where the membrane passes over the cornea, nothing was left but the epidermic layer. Glands (follicles?) had been discovered by M. Krause in the human conjunctiva. During health, the daily desquamation consisted of epithelial fragments, and of small cells, composing what M. Krause calls the lenticular glands; but when inflammation was present new cells were generated, and, in some instances, pigment. During this first period of inflammation, vessels did not necessarily form, but when their production became evident to the naked eye, when the transformation of the membranes was effected, the physician's art was of no more avail. The paper terminated with a theory of the paralysis of the recti muscles. The motor oculorum (third pair) arises from a gelatinous substance which M. Pappenheim had demonstrated in the corpora quadrigemina; in this substance might be found a rich plexus of capillaries which communicated with the vessels of the envelopes of the brain; hence, in meningitis, the frequency of paralysis of the recti muscles of the eyeball.

EPILEPSY.—M. PLOUVIEZ, of Lille, proposed for the treatment of epilepsy the extract of belladonna, exhibited in doses sufficient to produce a commencement of intoxication. The following was the prescription he employed:—℞. Extr. belladonnae, 5ss.; pulv. digitalis, 5j.; indigo, 5iijss.; mucil. q.s.f.s.s. pil. 50; one, two, or three, according to their effects on the system.

FRACTURE OF THE CLAVICLE.—M. GUILLON presented a child to the academy; it was the ninth case of fracture of the clavicle cured without deformation—an accident very difficult to avoid generally. The bandage consisted—1, in a sling for the support of the forearm and elbow; 2, a handkerchief folded in the shape of a cravat, one extremity of which was passed on the diseased side between the body and the arm, embraced the arm, and was solidly fixed to the sling; 3, an axillary cushion; 4, a broad *bandage de corps*; and 5, a square cushion to be fixed between the shoulders. M. Guillon then related two cases which induced him to believe that by appropriate means, and when the callus was not very solid, the natural rectitude of a deformed clavicle might be restored. The first case was that of a drummer of the National Guard, who fell five years since from a considerable height and fractured his collar-bone on the right side. The fracture was perfectly cured, and the case was shown at the Société de Médecine Pratique, and recognised as one unattended with deformity. Five weeks after the accident the patient returned to his duties, and the weight of the drum and sword bearing upon the right clavicle brought on a very well-marked depression in the original seat of the fracture. The second case was that of a child, aged twelve years, who, having fractured the left forearm eleven months before, fell upon the hands with great violence. The radius and cubitus were bent backwards at right angles in the spot which had been fractured. M. Guillon restored the limb to its proper direction by the use of considerable force, and placed the extremity in the bandage for fractures. One month afterwards the child was perfectly cured without deformity.

ACADEMY OF MEDICINE.

Meeting of Sept. 7; M. BROIN in the Chair.
DIFFERENCES BETWEEN TYPHOID FEVER AND THE
PLAGUE.

In January, 1846, a disease of a doubtful na-

favourable or even disagreeable result. To adults I have usually given a drachm of sulphate of magnesia, combined with a grain of ipecacuanha, in some simple aromatic water, every six hours; to children about half the quantity; and to infants a still smaller dose. I have observed, that so soon as natural fecal dejections are produced, the bloody mucosities cease to be discharged, the tenesmus disappears, and the patient is cured. In by far the majority of cases the bowels have been properly relieved within twenty four or thirty-six hours; but in a few cases of a more severe character the bowels have been more obstinate, and the saline purgatives have not produced their proper effect until after the lapse of three days. I have, also, occasionally observed the continuance of tenesmus after the proper action of the bowels; but this has been easily relieved by an opiate. The addition of small doses of ipecacuanha I have imagined to be beneficial from the known efficacy of this substance in several intestinal diseases; but I should place my chief reliance on the saline purgative. In practice I direct the patient to continue the medicine until faecal motions have made their appearance, and then either to take the medicine less frequently, or altogether omit it, as, without this precaution, severe diarrhoea might be induced. Where this plan of treatment has been adopted, I have not seen a single case in which the disease became chronic.

I am further desirous to know what would be the effect of saline purgatives in the more severe forms of dysentery in hot climates, although I have little doubt that similar good consequences would follow from its use; and I should feel extremely obliged if some Indian practitioner would make the trial, and give us the result of his experience.

I am, Sir, your obedient servant,

PHILIP B. AYERS, M.D.

Senior Physician to the Islington Dispensary, &c.
12, Howland-street, Fitzroy-square, Sept. 13.

ON THE INTERNAL USE OF THE
NITRATE OF SILVER.

By MR. RICHARD SOUTHERN, Cambridge.

The nitrate of silver being much more frequently prescribed than heretofore, it may not be uninteresting to some of your numerous readers to learn that the discolorization of the skin is not of that frequent occurrence generally supposed; in fact, large and repeated doses may be given without producing such effect. In the year 1831, when the cholera raged to a frightful extent at the port of St. Petersburg, I ordered it in grain doses in every case of collapse, and frequently repeated the same quantity every quarter of an hour, without in one instance discolouring the skin. This remedy was mentioned as being very successful, in the report of the Government Commissioner, Drs. Kussell and Barry, at the time; and I know of no medicine capable of producing reaction with so much certainty, though this sometimes was sudden and violent, requiring the immediate use of the lancet; and in several cases the inordinate excitement was difficult to suppress, but no discolorization followed.

CONGENITAL IMPERFORATION OF THE
URETHRA THE WHOLE DEPTH OF
THE GLANDS.

By E. WHITEHEAD, Surgeon, Dakin's Id.

Mrs. B. gave birth to a male child on Christmas eve, 1846. I called the following day, but no remark was made. Being a distance of a mile and a half, I omitted visiting on the second day, but intended doing so on the third. However, early on the morning of my intended call I was hastily summoned. On my arrival, I found the infant screaming vehemently, and apparently in great pain. Upon inquiry, I was informed that its bowels had been moved repeatedly; but the nurse could not say it had ever passed any urine.

Upon examination this was verified, the glans penis being imperforate; bladder considerably distended. Not having my pocket-case with me, I ordered the little sufferer to be brought to my house, where, assisted by my friend Mr. Hunt, surgeon, of Ashton-under-Lyne, an opening was made with a lancet in the place where the orifice of the urethra is usually situated, and an attempt made to pass a probe; the lancet and probe were again used, but without success.

The incision was then carried through the inferior length of the glans, upon which urine escaped freely. Not the slightest vestige of an opening could be found in the glans other than the one made by the operation, which was allowed to heal. The artificial outlet now supplies the place of the natural one.

CASE OF STRANGULATED INGUINAL
HERNIA.

Reduced on the New Method recommended by Dr. Andrew Buchanan, Professor of Institutes of Medicine in the University of Glasgow.
By ARCHIBALD WALLIS MACKIE, Cupar, Fife.

G. M., aged seventeen years, railway labourer, of a stout habit of body, and enjoying previous good health, whilst employed lifting some heavy railway sleepers on Friday last, felt something to give way at the lower part of his abdomen. The patient was unable to walk, and was carried to a neighbouring house, where he remained till next day, when he was conveyed to his father's residence, a distance of eleven miles. I was called to visit him on Sunday morning, and on examination found a tumour the size of a hen's egg, situated in the right iliac region, the general characters of which led me to conclude that it was a case of strangulated oblique inguinal hernia. The patient had not had his bowels opened since the morning of the accident. I ordered him an enema, and, after waiting till it was expelled, I applied the taxis, but unsuccessfully; I then had recourse to the usual remedies adopted in such cases, but without any effect. I thought me of the plan recommended by the talented Professor of Physiology in the Glasgow University, and I was glad to see my efforts crowned with success. The mode is very simple. I placed my patient on his back, flexing the thighs on the pelvis, and putting the muscles of the abdomen in as relaxed a condition as possible. I then desired the patient to empty his lungs of as much air as possible, and having an assistant at hand, who immediately held his nose and mouth to prevent inspiration, I applied gentle pressure over the tumour in the proper direction, and had the satisfaction to feel it give way, and, as it were, *draw up* into its natural cavity.

The rationale seems to me to be, when the lungs are emptied of air, the diaphragm is, as it were, sucked up to fill the diminished thoracic cavity; it (diaphragm) exerts a tractile power over the floating viscera of the abdomen, and draws the protruded intestine upwards—naturally assisting, if not altogether accomplishing, the reduction of the hernia.

Such is the mode, I conceive, in which the reduction is accomplished; and I have no doubt that, in addition to the mechanical influence, the temporary suspension of the breathing must have a powerful sedative effect, and consequently a relaxing influence, on any part morbidly constricted. Before operating I would always give this plan a fair and impartial trial, and I am confident, if practitioners would adopt this method, they would have the satisfaction of relieving their patients, and thus averting the dangers of a painful and often fatal operation.

APOTHECARIES' HALL.—Gentlemen admitted members on Sept. 9:—Henry Davis Wenwell, Robert Blairie, William Pritchard, Henry Davis, James Payton Badley, Joseph Thomas Clover, William Leyson Thomas, Polliott James Sandford and Thomas Horn.

ture was observed at Marseilles on a sailor. Dr. Renoult asserted it was a case of typhoid fever. The physicians attached to the Lazaret were of opinion it was an instance of plague. The Minister had forwarded the history of the disease to the academy, with a request that the society would express its opinion upon the nature of the complaint in the case alluded to; and, secondly, would examine into the resemblances and differences of typhoid fever and plague, and point them out. M. Prus, the reporter of the commission, in answer to the first question, said that the case observed at Marseilles was in all probability one of typhoid fever, although a bubo was present. Typhoid fever and the plague had numerous analogies, but also certain characteristic differences; for instance:—

In Typhoid Fever we find	In Plague.
Premontory symptoms	None.
Diarrhoea	None.
Lenticular spots	None.
Meteorism, and enterophony in the right iliac fossa	None.
Very rarely	Buboes.
Rarely	Petechiae.
Enlargement of the mesenteric glands only.	Enlargement of the lymphatic glands of the whole body.
Special and characteristic intestinal eruptions	Echymotic patches in the pericardium and pleura.

After a short and unimportant debate, the report and its conclusions were adopted.

CASE OF WOUND OF THE BRAIN—CURE BY DR. GINTRAE, OF BORDEAUX.

A boy, aged twelve years, fell, on Dec. 15, 1816, upon an open clasp knife which he held in his hand. He rose unassisted, and went to the infirmary of the school. M. Gintreae was immediately called, and found that the knife had penetrated between the eyeball and the upper eyelid, on the left side, at equal distances from the commissures, had perforated the orbital plate of the frontal bone, and was solidly fixed in this situation. Its direction upwards and backwards was inclined at an angle of 15° with the face, the back of the blade rested upon the eyeball, the sharp edge raising the eyelid. The child was unconscious when M. Gintreae first saw him, the skin cold, face pale, pulse imperceptible. The surgeon first endeavoured to remove the knife by drawing it cautiously downwards and forwards, without moving it from side to side. After several unsuccessful efforts, M. Gintreae was obliged to call his assistant to his aid; and, having fixed the head, at last removed the knife; the blade was eight centimètres in length, one in breadth, and had penetrated altogether five centimètres; during the extraction the patient had remained entirely insensible. After five hours he recovered his senses, could speak with freedom, and complained merely of slight pain in the orbit, unattended with headache. The child slept the next day he was almost well; considerable swelling of the lid persisted for several days, and after one fortnight the boy returned to his studies—neither vision, speech, nor intelligence having in the least degree suffered from the accident.

M. Gintreae, in order to determine if really the brain had been wounded in this case, introduced the same knife, at the same depth, into the orbital plate of the frontal bone of a dead subject; and, having afterwards opened the head, found that the instrument had penetrated eighteen millimètres (nearly six lines) into the anterior lobe of the cerebrum.

TYPHOID FEVER AND SMALLPOX. BY M. SERRES.

On a former occasion we mentioned the treatment which M. Serres considers most efficient in typhoid fever, viz., the black sulphuret of mercury; and, also, how the profession was led to adopt this method, from the good effects of mercurial preparations on the eruption of smallpox. In another communication to the Academy of Sciences the learned professor continues the same subject.

The intercurrent affections, says M. Serres, two diseases progressing at the same time in the same individual, each preserves its physiognomy, its special characters, although the intimate nature of both may have undergone a considerable modification. The most severe of the two almost invariably communicates its gravity to the other, and diminishes if it does not destroy the chances of recovery. In the treatment, therefore, of intervening disorders, the most dangerous must exclusively occupy the attention of the therapist; in order to judge a curative method, it should be put to the test of these intercurrent affections, and to this test I have submitted the method I propose for the cure of typhoid fever; and have chosen the most severe complication—variola. The dangers of confluent smallpox are known to all; vaccination has considerably diminished them, but within certain limits. Thus, at the Hospital of La Pitié, during the epidemic of 1825, out of 162 vaccinated subjects attacked by the epidemic, twenty-five died. From the statistics published by Dr. Bonsquet, it appears that in the thirty epidemics of smallpox observed in France between the years 1816 and 1811, 5963 vaccinated persons were attacked, and sixty-two died. Analogous results have been noticed in England, Germany, Italy, and Sweden. The revival of smallpox was attributed to the inefficiency of vaccination—a conclusion which we consider erroneous: "It is," continues M. Serres, "to the influence of intercurrent disorders that this impotency of vaccination to prevent variola should be attributed, and chiefly to typhoid fever. During the epidemic of 1825 we were struck principally by two facts: the first was the progress of the pustular eruption, which was the same in the vaccinated subjects as in those who had not been vaccinated; and the second was the presence in the intestines of the facial characters of typhoid fever. The epidemic, in one word, was double: it was at the same time varioloid and typhoid. The mortal influence of typhoid fever in cases of smallpox has appeared to us still more evident in cases of non-vaccinated patients. We may ask ourselves if, before the discovery of vaccine, the interference of typhoid fever was not one of the great elements of the danger of variola; and we will find in the symptomatic history of ancient epidemics abundant proofs that such was the fact. Typhoid fever is not, therefore, a new disease, but smallpox and typhoid fever were, perhaps, coeval: the cutaneous eruption of the former struck more forcibly the observer and concealed the complication. It would seem that, after Jenner's discovery, variola was in a great measure arrested, and typhoid fever, being unmasked, was at last recognised." After having established that in most cases the complication of typhoid fever was the principal source of danger in cases of smallpox, the learned professor proceeded to say that he had watched attentively the effects of the black sulphuret of mercury in such cases, and that, in proportion as the medicine relieved the symptoms of the typhoid fever, it also weakened the violence of the smallpox.

ANTIDOTES OF ARSENIC.—Insoluble salts of arsenic, after remaining a certain time in the stomach, are at last absorbed, and act as violent poisons. The cause of this fact is to be found, according to M. Caventon, in the presence in the stomach of a certain quantity of muriate of ammonia, by the action of which the arsenical preparation becomes soluble. In order to ascertain the different degrees of facility with which the muriate of ammonia dissolves the arsenites of lime, of magnesia, and of iron, M. Caventon instituted experiments, the result of which was to prove that the arsenites of lime was readily dissolved in 115 parts of a saturated solution of muriate of ammonia, the arsenite of magnesia in 330 parts, and the arsenite of iron in 600. Consequently the hydrate of sesquioxide of iron is the antidote which will resist for the longest time the dissolving action of the gastric fluids, and which it will be most proper to exhibit in the first place in cases of poisoning by arsenic.

D. MCCARTHY, D.M.P.

Amputation of the Penis.—M. Ricord recommends, that after amputation in the ordinary way, enough skin be left to cover the corpora cavernosa, and no more; the surgeon seizes with forceps the mucous membrane of the urethra, and with a pair of scissors makes four slight incisions so as to form four equal flaps; then, using a fine needle, which carries a silk ligature, each flap of membrane is united to the skin by a suture. The wound heals by the first intention; adhesions form between the skin and mucous membrane, and these textures become continuous, a condition analogous to which is observed at the other natural outlets of the body. The cicatrix then contracting, instead of operating prejudicially, tends to open the urethra.

Treatment of Hypertrophy of the Septum Nasi.—A boy was brought to M. Brulet, of Dijon, to be relieved of a tumour situated in the nasal fossae, which were obliterated by it. The tumour was of bony hardness, and situated close upon the external orifice of these cavities; it was manifestly developed in the cartilaginous septum, forming a hard plug of the size of a small nut. It was removed by separating the inferior part of the septum to its junction with the upper lip by a cut with scissors. All the hypertrophied part was then cut away with a tenotome, and reunion was quickly effected with one point of suture, and it was impossible to perceive where the operation had been performed.

Excitable Tumour of the Head of the Tibia.—A young woman was admitted into the Hôtel Dieu, of Toulouse, suffering from transient and indistinct pains in the left leg, which, however, did not impede the motions of the joint. Some time previously she fell from a chair and struck her limb, when the disease more plainly developed itself. A tumour was perceptible over the head of the tibia, which continued to increase. It was developed of irregular size, having two unequal elevations, incompressible but not painful. Pulsations were plainly perceptible isochronous with the arterial diastole; there was also a slight *bruit de soufflet*. Both ceased on compression of the crural artery. A ligature was applied on this vessel, and immediately the pulsation in the tumour ceased. Next day it was considerably decreased in size, but suppurative inflammation of the cellular tissue having supervened, with pleurisy, the patient died at the end of a week, after having miscarried. The *post-mortem* inspection showed a sero-purulent effusion in the left pleura, with compression of the lung. The cellular tissue of the thigh on which the operation had been performed was filled with pus, which had burrowed among the muscles in every direction. On removing the integuments from the tumour it was found to be hard and incompressible in some parts, fragile in others, and crepitating on pressure like dry parchment. In some points the bony tissue had disappeared. A division of the head of the tibia showed that the tumour was composed of a tissue of varied colour, being yellow in some spots, rose-coloured in others, and spotted so as to resemble a section of the brain. The mass of the tumour appeared to consist of two substances, one of a chalky white and inorganic, the other areolar. Occasional masses resembling brain were seen, as well as spots having the aspect of softened cerebral matter. The diseased masses had entirely replaced the spongy tissue of the bone, but the cartilage was unaffected. The solid parts of the bone were reduced to a complete shell.

Senna with Matico, in Hemorrhage from the Bowels.

—Dr. Watmough, of Pocklington, says that he has frequently used senna in cases of hemorrhage, and that he has combined it with advantage with senna in a case of typhus fever, when hemorrhage from the bowels took place. Matico and senna, in the proportions of two drachms each, were infused in a pint of boiling water, and a wineglassfull administered frequently. Scybala, mingled with blood, soon passed, after which the blood decreased; and by continuing the mixture in similar doses, at intervals, for three or four days, the alvine evacuations gradually improved.

Sulphuric Acid in Aphthae.—Professor Lippich,

of Padua, employs with success the sulphuric acid against aphthæ, and syphilitic mercurial stomatitis when the mucous membranes of the mouth and lips are covered with ulcerations which render deglutition difficult. The ulcerated surfaces are to be frequently touched slightly with the following liniment, by means of a soft brush:—White honey, thirty grammes; sulphuric acid, two grammes; mix. In severe cases the sulphuric acid may be increased to eight grammes.

Characteristics of Mercurial Sores.—Mr. Porter gives the following (in "The Dublin Medical Press") :—1. Mercurial sores are not necessarily circular or oval in shape, neither are their edges regularly defined, but assume different forms as they spread; their edges are often quite ragged, loose, and undermined, and their borders are often marked with a thin transparent cuticle, like that of a newly-formed cicatrix, extending quite around them, and giving them a silvery white appearance. 2. The bases of mercurial sores are not hard, neither are their surfaces covered with the tenaciously adherent lymph, so characteristic of venereal; but the surface may present every variety of shape and appearance, sloughy at one spot, deeply excavated and rapidly ulcerating at another, with exuberant granulations at a third, and exhibiting a tendency to heal at a fourth. 3. But the most striking characteristic of the mercurial sore is its tendency to spread, and the manner in which it enlarges itself. Venereal sores, when not affected by phagedæna, increase slowly, and having reached a given size remain so. The mercurial generally spreads quickly, and there seems to be no limit to the size it may possibly attain. Mercurial sores, too, are easily distinguished from the venereal when they assume a herpetic character, and heal in one part whilst they are spreading in another, which the latter never do: this latter diagnostic is often extremely valuable in ulcers of the throat and on the penis, when any extensive loss of parts may be most sensibly felt during the life of the patient. The mercurial ulceration, too, often attacks the cicatrix of a recently-healed chancre, and a fresh sore is thus formed—a circumstance that does not happen to the true venereal sore, except by some accidental injury, or the application of a new infection.

Warty Excrescences of the Eyelids.—Mr. Estlin, of Bristol, considers these to be diseased sebaceous glands, and that the most expeditious and least painful method of getting rid of them is to slit them through with a lancet or cataract knife, passed perpendicularly to their bases, and then forcibly to squeeze the separated halves, with the thumb-nails placed on the sound skin, till the contents are fully turned out; in two days the part is usually healed. The tumours, when thus removed, are found to be lobulated. If they resist considerable pressure, the loosened portion may be taken hold of with forceps, and thus the whole extracted. This practice may be employed when the tumours have begun to inflame or suppurate. Smaller ones usually disappear without treatment; their chief annoyance arises from the inflammation they occasion on the eyelids. Children are the chief subjects of this affection.

Bloodletting in Hemorrhages.—Mr. Hewson says, as hemorrhages seem to be stopped partly by a contraction of the bleeding orifices, and partly by the coagulation of the blood, and as the disposition of the blood to coagulate is increased by weakening the body, and likewise the contraction of the bleeding orifices is promoted by the same means, it is, therefore, evident that medicines to be used should be such as cool the body and lessen the force of the circulation; and experience teaches us that such are the most efficacious. It likewise shows that all agitation of mind and all bodily motion should as much as possible be prevented, because they increase the force of the circulation, and are thence unfavourable to the stopping of the hemorrhage. But that languor and faintness, being favourable to the coagulation of the blood and to the contraction of the bleeding orifices, should not be counteracted by stimulating medicines, but, on the contrary, should be encouraged. And, as evacua-

tions weaken the body more when they are sudden, we see a reason why bloodletting should be advisable in hemorrhages, and why a large orifice should be preferable to a small one when we want to produce the languor or faintness, or that weak action of the vessels so useful for the stopping of the hemorrhage.

Effect of Prolonged Interment on the Bones.—Some human bones having been discovered at Pantin, in the neighbourhood of Paris, M. Laigne endeavoured to ascertain their date by comparing them with bones of some soldiers who had been buried near them in the year 1814:—

	Unknown Skeleton.	Bones of 1814.
Water ..	20.0	20.0
Organic matter ..	11.0	15.0
Subphosphate of lime ..	45.1	40.5
Carbonate of lime ..	21.6	15.8
Sulphate of lime ..	2.3	—
Traces of oxide of iron ..	—	8.2

From these analyses it was concluded that the unknown bones were not so remote a date as was at first supposed.

Advantages of Compression over Ligature in Aneurism.—Dr. Hellingham, in his "Observations," &c., considers that compression is superior to ligature, because the mode in which he consolidation of the aneurism is brought about by compression is exactly the same as that in which a natural or spontaneous cure occurs; and, moreover, when a cure is effected in this way the vessel is obliterated merely at the site of the aneurism; whereas, when a ligature is applied in the usual situation, at some distance from the aneurism, the artery is obliterated both at the seat of the ligature and at the seat of the aneurism; but compression effects the cure of this disease by safer means than the ligature, because its employment can be intermitted and resumed according to circumstances, and no ill consequences have hitherto resulted from its use. On the other hand, the ligature of a large artery is always a precarious operation; when it is once applied, we must wait its separation before the patient can be considered out of danger; and when it fails, which frequently happens, the case almost always terminates unfavourably, not from the increase of the disease, but from the operation performed for its relief. Compression is more certain than ligature, for by this latter operation the aneurismal sac, and the part of the artery from whence it springs, are gradually filled up with fibrine separated from the blood and deposited in the same way as when nature cures an internal aneurism. Cure effected by compression is more likely to be permanent than when the ligature has been used, for pulsation cannot return after the employment of the former, as sometimes has happened after the latter operation. A cure brought about by this can only be permanent when it causes the aneurismal sac to be filled up and the artery to be obliterated at its seat, after the same manner as compression. If a loose coagulum of blood merely forms in the sac as the result of the ligature, there is danger either of the sac suppurating, or a secondary aneurism may form at the part, neither of which have ever occurred after the treatment by compression. Aneurism not unfrequently occurs in individuals in whom the coats of the artery leading to the sac are so much diseased that the vessel, instead of taking on the adhesive inflammation after the application of the ligature, ulcerates, or the ligature cuts its way through, giving rise to secondary hemorrhage. The disease, also, is not uncommon in individuals labouring under diseases of the heart and when more than one aneurism exists at the same time cases in which the ligature is contraindicated whereas pressure may be applied under these circumstances with nearly the same prospect of success as where the patient is perfectly healthy. Again, aneurism occasionally occurs in individuals who dread surgical operations so much that they cannot be induced to consent to them. Compression involves no operation, so that patients will probably make application at an earlier period, and thus will come under treatment at

a more favourable time for effecting a cure heretofore.

Development of the Teeth.—Mr. Hassall, in his "Microscopic Anatomy," says that preparations are made for the formation of the milk teeth at a very early period of intra-uterine life; that the first trace of the future tooth is manifested in form of a papilla placed in the primary dental groove, and consisting of granular and nucleated cells; that around this papilla a membrane is developed, with an open mouth, thus forming a follicle; from the margins of this aperture processes of the mucous membrane, of which the follicle is constituted, are developed, and these uniting with each other close the opening, and convert the follicle into a sac. With the closure of the mouth of the follicle, the first or follicular stage of the development of the teeth is terminated, and the second or saccular stage commences. The number of opercula developed from the margins of the follicles is determinate, being only two for the incisors, three for the canines, and four or five for the molars. In the second or saccular stage the papilla takes the form of the tooth, of which it is the representative, the base dividing, in the case of the molars, into fangs, and its apex assuming the shape of the crown of the tooth, in the place of which it stands; in this stage, also, a blastemic matter, consisting of plasma and nucleated cells, is developed in the space intervening between the papilla and the sac, and adherent to the inner surface of the membrane of the latter, by which, indeed, it is generated; lastly, the papillæ become capped with tooth substance, or dentine. With the passage of the teeth through the gums the saccular stage terminates, and the third or eruptive stage is entered upon. The second or permanent teeth pass through stages precisely similar to those of the first, or milk teeth, the papillæ and follicles being developed in crescent-shaped depressions, placed in the posterior walls of the follicles of the milk teeth, and which together constitute the secondary dental groove.

Membrana Jacobi.—On the outside of the granular layer (of the retina), observe Messrs. Bowman and Todd, in their "Physiological Anatomy," is that remarkable lamina, known by the name of its discoverer, the membrana Jacobi. It consists of club-shaped rods, placed uprightly, the thin end inwards, the thick outwards; and it is very easily detached from the rest of the retina, when the choroid is removed so as to float as delicate shreds, visible to the naked eye, in the water in which the eye is immersed. The rods have a tendency to separate from one another when placed in water, and the club-shaped extremities are then often seen to be formed by a sudden bending back of the stem like a crook, which may be more or less opened out. Interspersed among the rods are seen on the outer surface a number of clear spaces, as though transparent cells were disseminated among them. This layer forms the connecting medium between the retina and the choroidal epithelium.

Method of Extracting Pins from the Urethra.—M. Boinet employs the following simple process:—He first passes the finger into the rectum, if necessary, or presses it against the lower part of the urethra, so as to form a point of resistance to the head of the pin; the penis is then bent directly over the point, which is thus forced out through the sides of the urethra; the pin is then seized and extracted. No injurious consequences have followed.

Dislocation of the Hip-joint Reduced under the Influence of Ether.—Mr. F. Dehane records in "The Provincial Journal," the cure of a strong muscular man, who, while getting over a stile, his foot slipped, and falling, dislocated the head of the femur into the foramen ovale. The accident had occurred four days before admission into the dispensary. The limb was elongated to the extent of three inches, the heel elevated from the ground, the toes slightly everted, the knees advanced, and the thighs separated from each other; any attempt to handle the parts produced

exquisite pain. Prior to reduction, the ether was inhaled for about five minutes, when he became apparently intoxicated, but not insensible. He was placed on his back upon a mattress, the pelvis fixed with a towel, and the pulleys attached to the upper part of the thigh, and the usual extension made so as to remove the head of the bone from its abnormal position. In four minutes the head of the bone returned into its place with a sudden jerk. The patient did not appear to suffer much pain, although great force was gradually excited for its reduction; and he had the appearance of a person partially tipsy, and continued to talk and laugh through the operation.

Hair, Wool, Rags, and Thread expelled in a Mass from the Rectum.—Mr. Edward Spry, of the Royal Cornwall Infirmary, recently read, at the annual meeting of the South Western Branch of the Provincial Association, an account of the cure of a young woman, aged sixteen, who voided with excessive pain two large lumps of foreign matters—the first about the size of an ordinary pullet's egg, the second larger and longer—much compressed and very hard, having a thin albuminous coating which served to conceal the character of the contents of the lumps until forcibly separated. After being washed they were found to consist of dyed wool of various colours; of thread, of worsted, and of cotton and linen rags, all compactly fitted together, and weighing one ounce and four drachms. The patient had never from infancy enjoyed a good state of health, complaining of severe pain in her bowels. In September, 1846, when first attended by Mr. Spry, there was a considerable swelling just below the margin of the right ribs, and occupying the whole of the right hypochondrium. This tumour had a well-defined edge extending towards the epigastrium, and firm pressure on it occasioned pain. There were occasional vomitings. After the evacuation of the foreign substances, she steadily improved in health, and appears a fresh-coloured girl. It appears that this patient has no recollection of swallowing any part of the matters evacuated, but her mother stated that when a child learning to walk she could get at the seat of a settle in the kitchen, by the edge of which she held, and that the children often amused themselves by turning over the contents of a box in which old rags of all sorts were deposited; and that then the child must have swallowed the substances which after the lapse of many years were voided by the rectum.

Anencephalous Births.—Dr. Simpson states that, in his opinion, in anencephalous monsters the malformation arises from intra-uterine disease, viz., from the bursting of the head when hydrocephalic. The brain is opened up and distended by fluid so that it becomes gradually absorbed; at length the enclosing membrane gives way. The two small tubercles, always seen in anencephalous cases lying on the base of the cranium, seem to be nothing else than the remains of the membranes, shrunken up and almost obliterated.

REVIEWS.

Consumption of the Lungs and Asthma, Arrested and Cured, in the Majority of Cases, by Inhalation and other Rational Means; containing all the Remedies and Plans that are necessary in every Stage of those Diseases. Also the Means of Curing Influenza, Cough, Bronchitis, Sore Throat, Hoarseness, Inflammation of the Lungs, &c. By DANIEL CARR, M.D., Author of "Advice on the Diseases of the Stomach, Liver, &c., arising from Indigestion." London: Effingham Wilson, Royal Exchange, &c. &c.; pp. 200. Some people are very clever in their own estimation, but they are not content with holding this opinion themselves, they must have others think as they do in the matter. This is evidently the case with the author of the work before us, which is written for the twofold purpose of opening the eyes of the public to his merits as a

physician, and of increasing the number of his patients by showing them how they may doctor themselves. Of course Dr. Carr never intended that the book should be of use to any one but himself, and that by bringing patients to his house.

The thing is one of the oddest productions that has issued from the press in this remarkable age, having a titlepage which looks exceedingly like a quack advertisement, and a number of questions on the last leaf that have all the characteristics of a "Brummagem button." The preface shows us the singular modesty of the author, for there we are told that "many of the medicines are given from the writings of eminent practitioners, with some alterations that have rendered them more efficacious; while the peculiar feature of this book is the full information which it gives on the subject of inhalation: for in no other treatise in existence can there be found such particular and minute directions for the proper management of this important mode of treatment." The fame of Birmingham has hitherto been rather of an equivocal character, for while it has been celebrated for its artificers in brass, it has been renowned also for sending forth wares composed of a very base material with a very imposing aspect. We sincerely hope that our author will not prove a "Brummagem" doctor with pretensions so showy as for a season to pass current with the public, but which will be unable to withstand the test of science and experience.

We do not intend to dispute the fact that inhalation, under certain circumstances, may be usefully employed in diseases of the pulmonary organs, but we do not believe that, "when inhalation is not employed, all other means will be tried in vain." We could cite numerous instances to show the fallacy of this statement, but, as it is evidently made with a view to promote "puffing," we shall leave it without expending time and paper upon it.

In order that this "puffing system" may be carried on with advantage, patients must provide themselves, with glass inhalers, capable of holding about a quart, and the following articles:—Iodine, conium, hydrocyanic acid, ipæcacuanha, chlorine, morphine, lobelia inflata, stramonium, sulphuric ether, digitalis, belladonna, hyoscyamus, papaver, lactuca, black currant, colchicum, hoarhound, hyssop, red cabbage, hops, and other emollient herbs; vinegars, spirits of turpentine, tar; also some of the gums and balsamic resins." This is rather bold work to recommend unprofessional persons to have and to use such things as iodine, hydrocyanic acid, chlorine, and morphine; and we hope that even the doctor's friends will not be silly enough to tamper with their own lives, in preference to giving a fee for proper medical advice. Some of the remedies, however, may be employed with out incurring the risk attendant upon the use of chlorine or prussic acid; amongst these we find the decoction of red cabbage. This vegetable, we are told, "is possessed of great medicinal powers in consumption, and is used to greatest effect in the following manner:—Take of fresh leaves of red cabbage, cut into small pieces, three handfuls; boiling water, four pints; boil down to three pints, and add honey, two ounces; boil again, skim it during the time, and afterwards let the whole be strained. About a teacupful may be put into the inhaler at a time with a pint of hot water, and the vapour then received in the usual way, three, four, or five times daily. This composition will effectually diminish the irritation of the respiratory organs, lessen the cough, and facilitate expectoration. A teaspoonful of it may also be drunk internally three times a day (if it does not derange the bowels), and thus the system will receive all the benefit which this excellent remedy can impart." There is a certain kind of "irritation" with which knights of the shears are said to be troubled with, when engaged in making garments for the outer man, and which cabbage decoction recommended above will prove nothing inferior in allaying irritation of

the respiratory organs; the patient, however, must take care that the preparation be quite fresh, or the flatulence which follows will prove anything but comfortable.

We cannot imagine for what purpose this book was sent to a medical reviewer; the editors of provincial newspapers may give it a "puff," but the medical press must condemn it as a work which a doctor of medicine ought to consider beneath his dignity to write, as it can neither benefit the profession nor the public.

TO CORRESPONDENTS.

THE MEDICAL TIMES may be procured by an order on any Newsmen or Bookseller, or it will be sent direct by post from the Office of the Medical Times to Subscribers sending by a Post-office order, directed James Angerstein Carfrae, or an order on some party in town, One Guinea IN ADVANCE, which will free them for twelve months. Half-yearly Subscription, 13s.; Quarterly, 6s. 6d.

A Student.—The information sought will be given in the number about to be published. It does not affect the validity of the indenture, the master not being a member of the College of Surgeons in London.

An Old Surgeon.—The fee for a diploma of Master in Surgery, Glasgow, is £10. 10s.; for Doctor of Medicine, £25. 3s.

A Subscriber and Wellwisher.—There is no doubt that a fertile source of fever is the neglect of proper sanitary measures for clearing away the nuisances which exist in the densely-populated districts of large towns. Open drains, offensive and putrid matters, arising from animal and vegetable bodies in a state of decay, are permitted to send forth their pestiferous gales to the jeopardizing of the health and lives of both poor and rich. It is probable that some movement in the right direction will be made in Parliament during next session, though there will be a powerful opposition from interested parties. We shall not fail to use our best endeavours to aid the Government in any efficient measures they may bring forward to promote sanitary reform. The letter shall be used.

Medicus.—Chemistry and the microscope have thrown some light on the nature of miasmatic osium, but we know of no one having been so successful as to stay the progress of its frightful ravages by the use of medicines. The case, though thus suspicious to us, will be welcome.

A Licentiate.—The strictures on the Apothecaries' Society are under consideration, and may probably be inserted in a future number. We are unable to state the annual income of the corporation, or the number of prosecutions it has instituted against unqualified practitioners. We would advise our correspondent to apply to the secretary, at the Hall.

An Old Student.—The Royal Infirmary, Edinburgh, has some English students attending its wards; the fees are low, and the hospital is low. Edinburgh is a ruin, considered as a medical school.

Mr. J. Westmacott.—The severity of the remarks on certain parties may, for aught we know, be just, but it would be imprudent in us to publish them without a guarantee, as the inevitable consequence would be an action for defamation.

Mr. J. Richardson's suggestions will be attended to.

X. Y. Z.—Ether has been employed in the French capital successfully in the detection of simulated disease. We believe that M. Baudens was one of the first to use inhalation for this purpose.

A General Practitioner and Subscriber.—We are not ignorant of the tricks which certain itinerant quacks play upon the public. The most efficient remedy which we can recommend our correspondent to resort to, as they have visited his neighbourhood, is to get some of the injured patients to institute a prosecution.

F. R. S., West-end.—We have some doubts concerning the genuineness of the production, which personal interview, or a more satisfactory letter, as only remove.

A Member of the Institute.—*Mr. Pennington is a general practitioner, and is worthy of the highest admiration for the constant solicitude he has maintained for the welfare of his order.*

A Juvenile Correspondent.—*We do not remember having received the communication; if received it was overlooked amid the mass of correspondence which we have weekly to inspect. Write again, and it shall receive attention.*

Galen.—*The assistant-surgeon of the East India Company is required, as a condition to his appointment, to subscribe to the Military and Medical Retiring Fund, at his respective presidency, and also to the Military Orphan Society, if appointed to Bengal. The diploma of the Faculty of Physicians and Surgeons of Glasgow is received by the Board of Directors.*

A Parochial Medical Officer.—*The facts stated in the private communication received are of sufficient importance for publication. With the permission of our correspondent we will give them a place in our columns, as they will still further show the hard bondage in which gentlemen of his class are placed. "The lines of some country practitioners are not fallen in very pleasant places."*

A St. Thomas's Pupil.—*The lectures are in accordance with the Society's regulations, but the want of an indenture of apprenticeship will be a barrier to examination. The loss of the document, and the death of the master, can be remedied if there are no further difficulties to encounter.*

A Young Surgeon.—*There must have been some defect in the apparatus, or the mode of using it. The nostrils should be carefully closed, or the desired effect may not be produced. A common bladder of large dimensions has been used with success, but it has been objected to on account of the patient respiring carbonic acid exhaled from the lungs. There are apparatus constructed for the especial purpose of administering oxygen when required. Our correspondent had better see an experienced surgeon administering the ether before he attempts to do so himself.*

Ignoramus.—*The English word is derived from omoios, similar; and pathos, affection.*

We shall consider the communication of Mr. Thomas, of the Cumberland Infirmary, and if it does not expose us to an action for libel it shall receive an early insertion.

We are requested to correct a mistake in a former number of the Medical Times, in which it was stated that Mr. Crosse, of Norwich, had dissected many hundred ears of deaf and dumb persons. Mr. Toynbee is the gentleman who is entitled to this distinction.

French, Higham Ferrers, must stand over till next week.

A Hebdomadal Reader.—*There are certain periods of the year when candidates are examined at St. Andrew's for the doctor's degree.*

Mr. C. A. Dalby, Ashby-de-la-Zouch.—*Jac-nec and Ferrusson.*

Mr. Brandon, 3, Vernon-place, Bloomsbury, says that he has seen venereal ulcers cured by human saliva, and no secondary symptoms follow; also, ophthalmia tarsi, and foul ulcers on the finger. The effect, he says, is very quickly perceived. He adduces the corroboratory fact, that sores in days are rapidly healed in this way. We are aware that in the French army saliva is held in great esteem both as a curative and preventive of venereal sores.

J. B. O.—*A prosecution could be maintained against the parties mentioned, but it would not be advisable, the qualification being one sanctioned by the Legislature. The party also is entitled, we think, to professional courtesy.*

Letters and communications have been received from Mr. Nance, Ecclestone; Dr. Nicol, Inverness; Mr. Dalby, Ashby-de-la-Zouch; Mr. Coife, Muldreser Hospital; Mr. J. Gordon Bailey, London; Mr. Alfred Edmonorth, Bulwell, Notts; Galen; A Parochial Medical Officer; A St. Thomas's Pupil; A Young Surgeon; Mr. Oliver Thomas, Hopedale, Ferryside, Carmarthen; Ignoramus; Mr. Evan Thomas, Cumberland Infirmary; French, Higham Ferrers; A Hebdomadal Reader; Mr. Brandon, 3, Vernon-place, Finsbury; A Juvenile Correspondent; A Member of the Institute; F. R. N., West-end; A General Practitioner and Subscriber; Z. Y. Z.;

Mr. J. Richardson; Mr. Westmacott; An Old Student; A Licentiate; Medicus; A Subscriber and Well-wisher; An Old Surgeon; A Student; J. B. O.

THE MEDICAL TIMES.

SATURDAY, SEPTEMBER 18, 1847.

THE POOR-LAW INIQUITY.

MR. PRANKERD, in his manly and valuable letter, given in another column, says truly that neither Parliament nor the country have any sympathy for the wrongs of the medical man. Why? Probably not through disinterestedness. There is in them a sort of lurking conviction that they have the benefit of our losses. We are a community apart whom they would support, as a necessity, at the smallest possible cost. Hence, when we grumble, they "smile"; and when our complaints are reiterated, they absolutely "laugh"; for these are the happy assurances that they are successful—that they not only have doctors, but have them cheap.

This feeling, so naturally indicated to Mr. Prankerd by his guardians, is more general than is fancied. Parliament—in this respect the mirror of the public sentiment—has never displayed any anxiety to ameliorate our condition. The M.P.s are far from anxious we should rise in the social scale, or that with a higher science we should vindicate a larger usefulness. To set us right, or give us our legitimate position, are courses which take the shape of what they are rarely guilty—self-taxation. Through the poor on their estates, through their tenantry and their servants, they have the benefits of our injuries; and though there may hover about them a half-consciousness that what they gain in purse they will lose in the larger and more substantial advantages of greater health to themselves, and higher usefulness in one of the country's most important professions, still the immediate numismatic consideration is overwhelming, and like the safe spectator in "Lucretius," gathering personal comfort from observing the distant storm and its shipwrecks—they survey our grievances with a secret pleasure, and hear our groans with an unavowed delight.

This is quite natural, and would excite in us no regret if our friends gathered from it that lesson of self-seeking and self-reliance it so powerfully teaches. We are quite strong enough to attend to our own interests. We want no external aid, and if we will not use our own adequate means, we merit the indifference we are deploring. Our legislators are not the good-natured men to help those who will not help themselves. They act on the other theory themselves, and are entitled to resent as a personal affront the idle beseechings of powerful do-nothings. In the poor-law question, too, the living pauperism of the land is so much more deeply concerned than we, that we should be apathetic or indiscreet indeed if we failed to enlist for it a large amount of public sympathy and support. Ours is only a small part of the Government question. All that we can say is, that we are cheated—widely, continuously, and systematically. The poor are cheated too, but it is not so much in purse alone: it is in comfort, in health, in life. We suffer as the agents, they as the victims, of a bad system. For them, at least, there is sympathy and sup-

port; and, in doing justice to their wrongs, we adjust our own.

The public ought to know at once, that whoever the medical man may be, a system of half-payments can never secure a system of plenary attendance. There is a principle in human nature that stands up against the system, and in many, if not in most, men it will, more or less, sway and govern—whoever may suffer by it. "You, a guardian, complain that the duty is inefficiently done; but, being inefficiently paid for by you, you cannot consistently reprimand the fault; and if you do, the place is so little worth possessing, the holder may fling it in your face. You get more than you pay for—and, wherever be the falling off, the injustice is yours. If the union require a thousand hundredweight of meat, and you contract to pay but for the half, the starvations that follow lie at your door rather than at the butcher's. It is much the same with the medical officers. At all events, however wrong the doctor, you are still more so to place him in a position in which he can only be just to you by doing wrong to himself, or avoid the ruin of others save at the price of his own."

The Convention in London, attended by every union doctor, is the great clue that will extricate the profession from this labyrinthine difficulty. We shall then have secured unity of purpose and action in a large section of our brethren, which, observed by the rest of the profession, will guarantee assistance and sympathy, instead of jealousy, rivalry, and opposition. Thenceforward, in our battlings with commissioners and guardians, it will no longer be an obscure affair of individual hardship or contest: for the future to accomplish a single injustice in one district would be first to triumph over the resistance of all. A powerful enemy would find a still more powerful foe, and in every union doctor there would be—if ill treated—a defendant with five thousand backers. But, powerful to resist aggression, they would be equally so to secure further improvements. They would inform their own brethren and the public; they would diffuse a better knowledge of a subject yet much in the dark, and would operate by personal influence as by public exertions on men in power. We repeat, then, now is the time to be stirring; it is most favourable, and not a minute should be lost. *A conference of the union doctors of London is of primary and immediate importance.*

THE HULKS AT WOOLWICH—MR. DUNCOMBE'S CHARGES AGAINST MR. BOSSEY.

It is our anxious wish in all cases to see justice done to the members of the medical profession, as they are especially liable to have their best efforts slighted, and their conduct maligned without any just grounds. Reputation to them is all that is valuable: for this once taken away, nothing remains for them but future neglect and ruin. The public are too ready to believe an unjust insinuation; and, though in the end justice is always done, yet this is often after the infliction of much suffering.

Mr. Bossey, the medical officer of the Hulks at Woolwich, has been placed in a very painful and critical situation, in consequence of certain charges which have been brought against him by Mr. Duncombe, in the House of Commons. These charges originated with an inmate of the hulks evidently of unsound mind; but, having reached the ears of the honourable member for

Finsbury, he considered them of sufficient importance to call for a searching investigation. Doubtless, Mr. Duncombe's intentions were good, but we are compelled to say, they were not prudent, and they must have been the means of inflicting much mental suffering upon the gentleman against whom they were made though fully conscious of his own integrity. The result of the affair is that Mr. Bossey is entirely exonerated from all blame, the official commissioner and Sir G. Grey having both reported to the Legislature that in "no instance had either harshness or cruelty been proved against him."

We congratulate Mr. Bossey on the result of this investigation, as it leaves him without a stain on his professional character, while we trust that Mr. Duncombe will in future exercise a little more discretion before he introduces to the House of Commons charges against the medical officers of public institutions. He is, *de profession*, the people's friend, but the very circumstance of his being so, and the readiness which he exhibits to vindicate his clients, expose him especially to the danger of being imposed upon, and thus of inflicting an injury when, perhaps, upon redressing one.

A FANCY HOSPITAL.

[To the Editor of the Medical Times.]

SIR.—Your article on "The Royal Free Hospital" is curious. If founded on facts, the hospital is romantic: if sketched from fancy, the romance looks very like truth. Which is it, Dr. Marsden?

Supposing that your Gray's-inn concern is no isolated case, and predicting from what little has occurred in one hospital how much may occur in others, why, as we have had in the lay world "The Mysteries of Paris" and "The Revelations of London," should you not add (as a *feuilleton*, perhaps) "The Mysteries of a London Hospital," or "Revelations of Metropolitan Charity," and give the professional world a capital novel? What interest might be anticipated from working out such commonplace points as even my poor fancy extemporizes: thus:—

I.

How to form a new or support an old hospital—showing how needy men may make fortunes by the activity of their benevolence.

II.

What experience suggests as the best standing machinery for turning the religious sympathies of the public through the breeches pocket of a man of the world.

III.

How a projector's *chers amis* may find it worth their while and his, officially to serve the destitute poor.

IV.

How incurring or paying a swinging debt may equally prove a profitable transaction—the destitute poor not included.

V.

Whether an adroit system of bill-discounting might not prove a useful fructifier of charitable donations.

VI.

How far the "extreme-destitution" principle, so useful in admitting patients, should be extended to the letting in of auditors and other bosom friends to office.

Add to the above, for character's sake, a few choice professional schemers from the gaols, the billiard rooms, and the stews, and it must go hard with the dullest writer if he want either incident or plot for "a romance of thrilling interest."

A LOOKER FORWARD.

THE POOR-LAW DOCTOR.

[To the Editor of the Medical Times.]

SIR.—The principles and sentiments contained in your remarks of the 11th instant so fully coincide with my own, that I cannot refrain from responding to them, and expressing the long-cherished feelings of indignation with which I have beheld so many educated and talented members of our profession degraded and oppressed by the heavy yoke imposed upon them in the position of medical officers to the poor—a class of people who ought to be the peculiar care of an enlightened and benevolent public.

I have long, too, held the opinion that no reform can be expected but from the combined co-operation of all who feel its importance; and, as you justly say, "there should be no delay—we do not know a better moment than the present for an agitation of the question."

The public ought to be faithfully and fully acquainted with the unworthy mode of electing the medical officer at the least possible salary, without any regard being paid to the real requirements of the sick poor, or the way in which they are to be met. But I believe that such an appeal, if *unitedly and powerfully* made, must produce its merited result—a decided and complete reform—a remedy which equally meets the grievances of the suffering poor and the oppressed practitioner. This object, I do not consider, has yet been sought in the most effectual manner, medical men having generally brought their own complaints forward, when they should rather show how deeply the poor are injured. This lesson I learned when in attendance upon the Select Committee of the Medical Poor Relief in London, under Lord Ashley, in 1844, when I expected the grievances of medical men would have been prominently brought forward and reported on; but I soon found that the members of that committee had no sympathy for our profession any longer than they affected the poor; and this, I believe, is the public feeling now. Medical men have been so slighted and oppressed (which they have almost merited, or at least procured by their supineness), that the public cannot easily be roused to any wrongs they may express; though let it be seen that the paupers are injured by the medical arrangements, and a ready ear will be found from influential quarters, which, properly followed up, would achieve much good for our profession. Not that I would deprecate our own claims to the sympathy of our fellow-citizens, but I fear we shall meet with only a cold response, as long as men are found who will voluntarily, or by force of circumstances are compelled to, submit to the indignities under which we are now suffering.

To give an idea of the medical relief in this neighbourhood, I must briefly detail some of my own troubles. I have the care of a union workhouse. For nearly ten years I have had the care of part of the J. — Union, during which time the remuneration paid the surgeons has continued the same, although in my own instance, as well as of others, the duties have increased nearly twofold. The salaries paid are generally on a lower scale than most unions in the county of Somerset, and very unequal to the duties required. I have several times made application to the guardians for an advance of salary, but have been invariably denied, until the commencement of the present year, when, in consequence of an inquiry from the poor-law commissioners, the salaries of some of the medical officers were slightly raised—my own district to the sum of TEN SHILLINGS annually!!! This district contains a population of 4567, has an average of 13,600, and during one year I registered 870 cases of sickness, for which I received the sum of £18. I registered, also, 2412 attendances at my own and the paupers' residences, travelling about 1500 miles, giving me, as remuneration, *one shilling and a penny and a fraction of a farthing* per case of sickness, and *fourpence halfpenny* for each attendance (it may be of eight or nine miles' ride to

and fro), besides the supply of medicines, which are very expensive—such as quinine, bark, opiates, &c. &c.

The majority of the cases treated were such as arise chiefly from bad food, with too much work, or from living in low, damp situations—as the following summary will show, viz.:—

Epidemics, endemics, and contagious diseases—Typhus, and remittent fevers ..	118
Scarlet fever 25, ague 13, diarrhoea 39, measles 19, dysentery 4, cholera 2 ..	102
Diseases of the nervous system—Chorea 4, epilepsy 6, hysteria 6, insanity 3 ..	19
Various affections of the head 33, diseases of the respiratory system 56 ..	89
Diseases of the circulatory organs 1, ditto digestive—viz., worms 46, teething 7 ..	54
Jaundice 1, dyspepsia and various affections of the stomach 180 ..	181
Urinary organs 10, generation 26, skin 116, rheumatism 27, dropsy 7, debility 19 ..	207
Surgical—Eye 17, abscess 16, ulcers 17, amputation 1, rupture 3, fistula 1, ..	55
Various injuries of different regions 41, miscellaneous cases, 4 ..	45

870

The medical man being so ill remunerated cannot possibly afford, on the salary given, the proper medicines and attendance, consequently, by a false economy, the poor, I am convinced, in very many instances, are kept in a state of suffering and distress longer than they should, and the ratepayer is longer burdened by the support of the sick pauper. During the present year I have already registered 690 cases of sickness, and one-half and more of my yearly contract is still unexpired; of this number are 212 cases of ague—a number considerably less than I really attended, as the labour of registering such a multitude of names was more than my assistant could well accomplish. I calculate, therefore, the cost of the quinine administered amounts nearly to the salary I shall receive: this great outlay was mentioned once at a meeting of the board of guardians, when it was received by an incredulous smile from the chairman, and a loud rin from several of the guardians.

The gross absurdity of the poor-law medical arrangements will be seen in the following table, where, taking similar districts in population and acreage, the great disproportion paid for the services rendered in the different unions of this county will be apparent.

Union.	Population.	Salary.
Langport	1506	£10
Bridgwater	1626	27
Taunton	1678	30
Shepton	1320	27
Frome	1436	28
Axbridge	1806	35
Langport	2758	30
Dulverton	2222	50
Wincanton	2283	43
Taunton	2164	45
Yeovil	2836	45
Dulverton	2805	55
Bridgwater	2924	48
Frome	2991	55

All Agricultural Unions, or, rather, Districts.

Again, an adjoining union pays 2s. per head for vaccination, this union pays 1s. 6d. per head, and the next union to this pays but 1s. for the same duties. I have, myself, to vaccinate children living six miles from my residence, and am expected to see the child twice, giving at least twenty-four miles to be ridden over.

It will naturally occur to your readers why, as a practitioner of upwards of ten years' standing, I should subject myself to such treatment? I simply reply, that, if I will not consent to the arrangement, another medical man would be introduced, which may materially affect my private practice; and the neighbourhood being a poor one, this would not be desirable.

I have, however, seen a few reforms in the system, and I live in the hope of seeing still greater, when our posts will be really honourable, rather than as they now exist—degrading to our-

selves, disgraceful to the *poor-law* officials, and most *iniquitous* to the *poor*.

Our profession to the *public* is most self-denying and liberal—to ourselves most selfish; every one follows his own interest, and cares little for the mass. We are so divided by the varied qualifications of our ranks, that our labours have been depreciated by public authorities; and the so-called *heads* of our profession have never stirred in our defence, but have left us to our fate.

The only plan which can satisfy medical attendants of unions must be a fixed rate per head on the whole population, allowed by the commissioners, from which the guardians cannot deviate. This, together with the additional rates granted by the medical order of March, 1842, and a medical commissioner for arbitration in all points relative to medical relief, will, I believe, satisfy the profession generally; and this, through perseverance and unanimity, I trust we shall obtain; and if you, as editor of a widely-circulated and valuable publication will further the cause with your sanction and exertions, the grateful thanks of an oppressed class of brother practitioners will be your reward, with the satisfaction in your own mind of being the best friend of the union doctor, and a *real* guardian of the poor.

I am, Sir, your obedient servant,

JOHN FRANKERD, M.R.C.S.E. and L.A.C.
Langport, Somerset, Sept. 15.

P.S. I may perhaps add, that I have the care of a union workhouse, at the salary of £32 per annum, whilst in the adjoining union £50 is paid for similar services.

DEGRADATION OF MEDICAL OFFICERS.

[To the Editor of the Medical Times.]

SIR,—I arrived at this place last week, with the intention of offering myself as a candidate for the office of house-surgeon to the hospital in the town; but, after some inquiries into the state of its affairs, abandoned that intention, and now communicate to you what information I obtained with regard to that establishment.

I confess that it startled me to find, on the outset of my inquiries, that, although the hospital has been established only five years, there have been *four* elections of house-surgeons, and a *fifth* about to take place. Upon further investigation my wonder ceased; and, feeling that the situation would not suit me, I did not offer myself; nor can I imagine how any man with a spark of gentlemanly feeling could condescend to the degradation of such an office.

It appears that the house-surgeon is nothing more than a mere dispenser, which any druggist's shopman would be fit for, as well, or better, perhaps, than an educated man, for he is to have nothing whatever to do with the management of the cases beyond spreading plaisters and compounding the medicines ordered by the physician and surgeons. If he venture to act upon an emergency, and suspend the administration of such medicines as foxglove or arsenic—the effects of which, by accumulating in the system, are injurious, and it may be fatal—he is liable to be visited by the wrath of the physician; or, if a man is suffering from agony from too tight a bandage on an inflamed limb, he must not remove it for fear of the high displeasure of the surgeons; and it is entered in the committee-book, that “the house-surgeon is not to prescribe a second time (even) for a casualty.”

Again, there is a standing order in the book of the said committee, that “the house-surgeon must not order any medicines from the druggist without the sanction of the physician or one of the surgeons.” Have the former in-door officers been dishonest? Have they been suspected? Such an order would naturally give rise to some misgiving on that head; if not, why, then, the order is a direct insult to them. The richest part of the story remains to be told. This said sapient committee have decreed that the gentleman who may be elected shall “give a bond or

undertaking to retain the office for three years; but the committee may dismiss him at any time.” Hence, the natural implication is, that if he should retire, in order to better himself by a partnership or public appointment, within the three years, he leaves his office in disgrace. The agreement is not mutual, and the gentleman is in a worse condition than a menial servant who stipulates for a month's warning on both sides. Does not this also imply that the committee fear lest the character of the institution should, by its frequent changes of its in-door officers, be in such bad odour that gentlemen will not come forward to fill any vacancy which may happen. And, therefore, they determine to nail one poor devil for a specified term to escape that imputation.

Now, what are the advantages to be derived from the office? Is it salary?—That is only £60 a year with board, for the combined duties of house-surgeon and secretary. Is it the hope of distinguishing himself, and gaining a *locus standi* in the county?—Alas! beyond the walls of the house, and a weekly summary of the killed and wounded in the county papers, he is unheard of. Is it instruction and furtherance in the knowledge of the profession?—The surgeons may be respectable practitioners, but their fame has not extended beyond the hills which surround the town; and the chances are that the young men of the day may rather instruct the surgeons. Is it personal peace and comfort?—Why, he is more likely to be knocked about as a shuttlecock between the surgeons, who are not on speaking terms; and, if he is civil to one, the other is sure to take offence at a supposed preference given to the other.

Is there not everything here calculated to discourage an educated man from accepting such an office?

“I'd rather be a dog and bay the moon,
Than such” (an officer).

I cannot find, upon inquiry, that these orders of the committee are sanctioned by the great body of the subscribers, and sincerely hope that, for the sake of an institution calculated for much usefulness, the first annual meeting will discontinue a system of management calculated only to overthrow it.

I remain, Sir,

Your obedient servant and constant reader,

ARCHIBALD CHRISTIE.

Dorchester, Dorset, Sept. 4.

SURGERY AT THE ROYAL FREE HOSPITAL.

[To the Editor of the Medical Times.]

SIR,—I am not one of those literary characters called Fellows, neither do I reside in that atmosphere of science which exists, as a matter of course, nowhere but in the great metropolis and its suburbs, but I am a poor benighted country practitioner, and, as such, may no doubt lay claim to your generous sympathy.

Being myself no critic, I will ask your opinion upon some cases, published by Mr. Weedon Cooke, of injury to the head treated by Mr. Wakley, jun.; and if you should agree with me that they have been carelessly reported and miserably mismanaged, however much Mr. Wakley, sen., from his atrocious conduct towards you and the *Medical Times* on all occasions, may have incurred your displeasure, do not let that induce you to be unjustly severe in your censures on the practice to which I shall draw your attention.

In a journal of July 3rd there is a report from the Royal Free Hospital, containing two cases treated by Mr. Wakley, jun. To the first of these I shall make no allusion, except in so far as to remind you that Dr. Lockhart Robertson has made some remarks upon it in reference to insanity. The second case is that of Wm. R., aged ten, who was “knocked down by a horse and chaise. The wheel passed over his head.” It is stated that “on the right side of the head, in the situation of the parietal eminence, there

was a straight wound of the scalp, an inch and a half in length, and gaping about half an inch; small quantities of brain were coozing from it; the finger discovered a fracture, with depression of a portion of bone, nearly an inch square, and the middle meningeal artery was felt pulsating distinctly.”

It must be remembered that the accident occurred on the 8th; that the trephine was not used until the 15th; that bread and butter were allowed on the 9th, and no preventive treatment had recourse to. The symptoms on his admission I must admit were not very urgent; but, considering all the circumstances of the case, I will ask you—1. Whether it was treated according to the established principles of surgery?—2. What could the arteria meningea media be doing opposite the parietal eminence?—3. Supposing it or any of its branches to have been there, was it wise, in a case of compound fracture of the skull, with depression to such an extent as to allow of the pulsation of the artery being felt, to leave the bone pressing upon and irritating the dura mater for seven days, until symptoms supervened, without applying the trephine, and this without using any preventive measures?—4. Was it safe and judicious to give bread and butter on the second day?—5. Is it possible that any brain could have escaped at the time of the accident, and the dura mater be found sound at the time of the operation, and after the bone had been pressing upon it for seven days?

What would the great and ever-to-be-admired Sir Astley Cooper say, if he could make his appearance once again, on finding the principles which he laid down for our guidance in such cases totally disregarded?

Your obedient servant,

A COUNTRY PRACTITIONER.

Gotham, Sept. 8.

NATIONAL CONVENTION OF POOR-LAW DOCTORS.

[To the Editor of the Medical Times.]

SIR,—In my last letter I dwelt on the inadequacy of my salary to the amount of duty performed towards the paupers in the district over which I have been appointed medical officer. I shall now consider the salary and duties of the union workhouse doctor, and show, by reference to my own, that in these houses of industry, as they are called, we have an equal excess of duty, an equally parsimonious remuneration.

In large unions the houses for the reception of, and testing, destitution are necessarily coextensive; and in proportion to the ever-changing inmates does disease exist of every description to which flesh is heir to. Fever of a malignant and fatal character is now the prevailing epidemic, dealing death to many of the attendants—surgeons, relieving officers, nurses, masters, matrons. And, in the past year, how many epidemics have reigned triumphant in these over-crowded, ill-ventilated pesthouses! Call we to mind our last year's trouble, anxiety, and care—our journeys without end, our patients without number. The wards have been filled with the worst class of cases with which medical men have to deal: destitution in the first place, and inflammatory attacks superseding. The over-crowded state of the houses has necessarily entailed great increase to our duties, yet we have no guardians volunteering an increase—no thanks from the community. We may visit the beds of sickness from hour to hour, and imbibe the poison emanating from the dead and dying; we may sacrifice health, and even life, for £15 per annum! God save the mark. For this magnificent sum is a perfect hospital maintained; concentrated, in fact, are several hospitals, for we have our *fever, lying-in, lock, smallpox, itch, and idiotic wards*; and maintained, too, in all their completeness, as far as advice and drugs are concerned. I believe, if I were to add together the number of patients in the sick wards during the past year afflicted with every kind of disease, from open facial cancer to

gangrene of the foot, I should find 400 regular hospital cases, though of a far worse description. Do these diseases require no medicines? Far more than the ordinary complaints we meet with out of doors. For the long-continued depression after fever, we want our quinine; for the pain of cancer, our morphia; for chronic enlargements, our potass. iodid.: all expensive drugs, and to be freely used. To be successful, we want our leeches and every convenient appliance, and yet we have no more allowed to us than will actually repay the cost out of our pocket. We have established fully our position, that our present salaries are totally unfit for the performance of such onerous duties, and I, for one, will gladly volunteer to join any movement which may be made to form a National Convention of Medical Men connected with the various unions throughout England. Something must be done, and that soon, for so long as the present dastardly system is upheld—until a thorough revision of it takes place—the sinews of the labouring poor will be wasted through inattention, or weakened by neglect. Raise the medical men to a proper level, give them the wherewithal to exert their utmost with, and we shall soon find less pauperism resulting from disease—more happiness amongst our poorer brethren. I feel pretty sure that the medical men are not at fault for accepting these offices, because in all advertisements the guardians carefully keep back from view the extent of duties to which the office is liable: they give the salary and the number of parishes, but never state the average number of patients, or the average number of acres to be ridden over. Thus the medical man, before I took to the district, had about eighty patients a quarter; but in the first six weeks I had actually 250 orders on me for medical attendance. If a district does contain such an extensive pauper population as to render the medical man liable to such an excessive amount of attendance, the fact should be advertised openly, and then I am sure the competition for these appointments would not be so great as to excite the ridicule of the guardians. How difficult it is to please all parties may be instanced by the fact, that two medical men have been dismissed from this district for inattention. Now, I believe the fact of the matter which led to this untoward result was their real inability to provide horses of good mettle enough for the work; and after they had held the district some time, they disregarded the patients, seeing the total absurdity of being able to repay themselves for their excessive exertions. *If a man is not a "bankrupt" before he takes to a union, he will stand so long as his druggist will give him credit, and no longer.* It is no disgrace to be dismissed from the poor-law commission, as surgeon, for in every case I have known, sympathy has been excited in the surgeon's favour, and one exclamation alone is uttered, "How could he be expected to work for nothing!" After dismissal an interest is excited, and the surgeon generally does better without than with the appointment. I am afraid I have exceeded my limits, so conclude with a fervent wish that some influential members will commence a movement toward the formation of a National Convention of Poor-law Medical Officers; and, should any venture to the fight, you are at liberty to enrol my name amongst the number.

I remain, Sir, your obedient servant,
A POOR UNION SURGEON.

THE FIRST WRITER ON SMALLPOX AS A DISTINCT DISEASE.

[To the Editor of the Medical Times.]

SIR,—In a late number of the *Medical Times*, a correspondent wished to be informed who was the first medical writer in England of any note that mentioned smallpox. I had this reply ready to send, the following week, but, having to leave town, was prevented posting it. In the mean time, some reader had replied that Sydenham was the first who treated it as a distinct disease from measles. Of this there is no doubt, but I do

not think it a reply to the question: for there were many who wrote about it long previous to that great man's time. A few I shall mention below, but I may remark that no writers previous to the thirteenth century wrote about smallpox, at least no works have come down to us; and this may justly be considered the time when it was first noticed in England.

One of the earliest, if not the earliest writer on this disease in this kingdom, was Bernard Gordon, a man of much reputation; he was a Scotchman, and practised at Montpellier. He wrote about the commencement of 1300. His "*Lilium Medicinæ de Morbis prope omniū Curatiōne*," &c. &c., is well known; and in another work by him, called "*Practica Gardonii*," there is a chapter on smallpox, which, as usual with all writers previous to Sydenham, as your correspondent justly observes, he treats as only a variety of rubeola. His works must have been much

must own, was to all intents a thorough quack; he lived in 1320. He was educated at Merton College, Oxon, and there took his M.D.; he was like many of the present day—so long as he made money, he cared not by what means. Besides his writings, which treat of everything, either in medicine, cookery, or the treatment of the hair, we have an instance of his mode of treating smallpox. When sent for to a son of either Edward I. or II., and who had this disease, he effected a "perfect cure without a mark," by rolling his patient in red cloth, and hanging red cloth about the bed! However, he was no small person in his time, and even Chaucer speaks of him as a clever man!

Another early writer, though of a latter date, was Tobias Whitaker, M.D., physician to Charles II.; he wrote a book in 1661—"An Elenchus of Opinions concerning the Cure of the Smallpox," &c.

And a very few years after (1666) the immortal Sydenham published his first work, being "Observations on Fevers."

Dr. Clinch, in 1724, speaks of a curious manuscript by "Mr. John Arden, surgeon to Richard II. and Henry IV.," noticing smallpox.

In 1593, Simon Kellwaye, gentleman, wrote and published "for the love and benefit of his country," a work entitled "A Defensative against the Plague," &c., "and whereunto is annexed a short Treatise on Smallpox, showing how to serve and help those that are affected with it."

But here I must stop, with many apologies for taking up so much valuable space in your journal.

I remain, your obedient servant,
J. ROBINSON CHAPMAN.

STRAIGHT SPLINT IN FRACTURES OF THE THIGH.

[To the Editor of the Medical Times.]

SIR,—Having observed in the number of the *Lancet* for July 10 a description of an extending straight splint, for the treatment of fracture of the thigh, by Mr. Bottomley, surgeon of Croydon, I beg leave to remark, that as long ago as the year 1811, I published in "*The Provincial Medical Journal*," an account of a similar apparatus, if I may judge, at least, from that gentleman's illustrative drawings.

It was constructed, as will be seen by my descriptive paper in that journal, by Mr. Laundry, formerly a surgical-instrument maker in the Borough, who highly approved of my suggestion, and requested his name might be mentioned as the maker of the apparatus.

I did not publish it, however, as the account of an invention, being aware that the peculiar mechanism for extension by the endless screw had been employed, although in a different manner, by M. Boyer; but mainly for the purpose of describing an additional small splint, which I thought would be useful in preventing the ex-cursion of the femur, which sometimes follows

these accidents. I also suggested the substitution of a padded leather crutch-band, in lieu of a circular band round the chest (as represented in Mr. Bottomley's drawings), which I had previously tried, but found to fail in producing the necessary counter-extension. An account of both these additions, as well as of the original apparatus, was published in the above-mentioned Journal for March 13, 1811.

Since that period, I have constantly employed the apparatus in the Royal Berkshire Hospital, and have, moreover, had several similar ones constructed for some medical friends in London and different parts of the country, who approved of this method of treating fractures by extension.

In the year 1846, finding that extension only by the foot, in several cases which I had treated in this manner, had appeared to produce a consecutive weakness or looseness of the knee-joint, by the long-continued stretching of its ligaments, I adopted a means of dividing the necessary amount of traction between the foot and the broken femur, by fixing a band round the lower part of the thigh, just above the patella, from which a strap passed to the foot-board or shoe, and was there fastened; and thus, on extension being made by the screw, an equal amount of traction was exerted upon the foot and upon the femur, which seemed to prevent the inconvenience in question. This alteration was the subject of a paper read before the Berkshire Pathological Society, and was duly recorded in the Annual Retrospect, in which it is thus mentioned (a):—

"Mr. F. A. Bulley exhibited an apparatus, which he had lately constructed for the more efficient treatment of fractures of the thigh-bone. The mechanical extensile power in this apparatus, by means of a footpiece moving on an endless screw, was so arranged that the necessary traction should be equally divided between the foot and the lower end of the fractured bone, because he had found that in many cases he had witnessed, where the extension had been practised wholly by the foot, the knee-joint, from its having been kept for a long time upon the stretch, had remained inflexible and useless long after the bone had been united; which constituted, he thought, a serious objection to this mode of treatment. He, therefore, proposed to remedy these inconveniences by a division of the tractile forces, so that half should be expended upon the thigh-bone itself, and half upon the foot. The peculiar mechanism of the apparatus would ensure these effects."

I beg to apologise for having trespassed thus much upon your valuable columns; I should not have done so, however, if I had not considered that I had a claim by priority of publication to this invention (if such it may be called), and the credit of introducing it to the notice of the profession, in point of time, long before the appearance of Mr. Bottomley's paper.

I have the honour to remain,

Your obedient servant,
F. A. BULLEY,
Surgeon to the Royal Berks Hospital, Reading.

BURIAL IN TOWNS.

On Wednesday evening last a public meeting was held at the Crown and Anchor Tavern, in the Strand, for the purpose of petitioning the Legislature for the abolition of intramural interments. The attendance was very large. B. B. Cabbell, Esq., M.P., occupied the chair, and, after briefly stating the object contemplated, called on G. A. Walker, Esq., to propose the first resolution.

Mr. Walker entered into many details in reference to the practices in London graveyards, and, in the course of his address, stated that whereas a hundred and thirty-six adults were universally acknowledged to be the maximum number which an acre is capable of adequately

(a) "*Provincial Med. Journal*," vol. ix., p. 449.

containing at one time, there were cases in London where three thousand bodies had been buried in that space. After citing numerous burial statistics, he moved the first resolution, condemning burial in towns as a violation of right feeling, and injurious to the public character, morals, and health.

Mr. Charles Shaw followed, and compared the practice of the present day with the old Roman law, "No dead man shall be buried in the city."

Mr. T. P. Healey supported the resolution. He condemned the prevalent practice of churchyard burial as exhibited every day in the public thoroughfares as out of harmony with the sacred and salutary feelings peculiar to the hour when we consign the remains of a loved object to the tomb. The religious of Christian interment as now presented were harshly contrasted with the steady probability of speedy succeeding disinterment, a proof of the system of removal of bodies from the graveyards. The few hurried burying places in the metropolis might be regarded also many conspiracies against the public health, which they were daily destroying by their continual exhalations. These mephitic vapours, where not sufficiently concentrated to cause immediate death, were productive of disease; and, as all impairment of health was an impairment of weekly wages, in the end the working men was carried to the grave whence he drew his death, leaving his family to the adverse chances of a world in which he had been so deeply wronged. It was a duty to rescue the families of the poor from such a fate, which was only the symbol of graver moral evils.

Sir C. Aldis moved the second resolution, declaratory of the increase of intermural interments, and demanding a supervision of burial places, and insisted upon the danger to be apprehended from the practice.

Mr. Stevens, Mr. George Ross, Mr. Richard Twyler, Mr. Rogers, and other gentlemen, addressed the meeting. A resolution appointing places to receive subscriptions was passed, and a petition to Parliament agreed to, when the meeting separated with a vote of thanks to the chairman.

GOSSIP OF THE WEEK.

THE FUNERAL OF SIR RICHARD DOBSON, KNIGHT.—This distinguished and much lamented officer, Sir Richard Dobson, Knight, M.D., F.R.S., &c., Knight of St. Vladimir of Russia and also of Dannebrog of Denmark, and Inspector of Hospitals and Fleets, was, on the 9th inst., buried with due honours at St. Mary's Church, Chatham, in the presence of a large concourse of people. The body was brought from London by a special steam-boat, accompanied by a distinguished circle of private friends as mourners; and the party having disembarked at the Sun pier the body was placed in a hearse drawn by four horses, the friends following in four mourning coaches with four horses each. At the church the body was met by the Rev. G. E. Nash and the Rev. H. T. Stimpson, and the following distinguished officers of the Royal Marine corps in full-dress uniform, namely:—Colonel John Wright, K.H., Commandant of the Royal Marines; Colonel Charles Menzies, K.H., second in command of the battalion; Dr. W. Rae, deputy inspector of hospitals and fleets, and chief medical officer of Melville Hospital; Dr. Warden, senior surgeon of the navy; Captain Alexander Anderson and Captain P. Trant Payne, of the Royal Marines. These six officers officiated as pall-bearers. There were also upwards of thirty officers of the Royal Marines in full-dress uniform stationed at the entrance of the church gates; and on the approach of the body they formed into open line for the corpse to pass through, and at the close of the procession they closed and walked two abreast into the church, when the funeral service was impressively read by the Rev. G. E. Nash. The

body was at the conclusion removed to the family vault. The deceased, owing to his distinguished character in the service, was much respected by the principal officers of the garrison. His gallant officer's service commenced in May, 1790, at Haslar Hospital, and in October, 1799, he was appointed to the Tickle, and in succession to the Arrow; Sans Pareil, Prince of Wales, Virginie, Swift, and Lively; and in 1809 he was appointed to the Trusty hospital ship, stationed in Gillingham-Reach of the river Medway, where he had charge of upwards of 1500 prisoners of war of all nations for five years. At the conclusion of that service he received the above orders of knighthood from the Emperor of Russia and King of Denmark, and also two magnificent diamond rings of the value of £1000; and in 1814 he was appointed surgeon of the Chatham division of the Royal Marines; and upon his appointment to Greenwich Hospital in 1821 he was presented by the officers of the Royal Marines with a valuable service of plate. He continued as chief medical officer and surgeon of Greenwich Hospital until June, 1844, when he retired on full pay. From the time of his entering the service to his retirement was forty-nine years and one month, during which he was forty-eight years in active service.

JENNY LIND AND HYPNOTISM.—On Friday last, the 3rd instant, Miss Jenny Lind, accompanied by Mr. and Mrs. S. Schwabe, and a few of their friends, attended a *seance* at Mr. Braid's, for the purpose of witnessing some of the extraordinary phenomena of hypnotism. There were two girls who work in a warehouse, and who had just come in their working attire. Having thrown them into the sleep, Mr. Braid sat down to the piano, and the moment he began playing, both somnambulists arose and approached the instrument, when they joined him in a trio. Having awoke one of the girls, Mr. Braid said, although she was ignorant of the grammar of her own language when awake, that when in the sleep she would prove herself competent to accompany any one in the room in singing song; in any language, giving both notes and words correctly—a feat which she was quite incompetent to perform in the waking condition. He requested any one in the room to put her to the test, when Mr. Schwabe sat down to the instrument, and played and sang a German song, in which she accompanied him correctly, giving both notes and words simultaneously with Mr. Schwabe. Another gentleman then tried her with one in Swedish, in which she also succeeded. Next the queen of song, the far-famed Jenny Lind, sat down to the instrument, and played and sang most beautifully a slow air, with Swedish words, which the somnambulist accompanied her in, in the most perfect manner both as regarded words and music. Jenny now seemed resolved to test the powers of the somnambulist to the utmost by a continued strain of the most difficult roulades and cadenzas, for which she is so famous, including some of her extraordinary *soubrette* notes, with all their inflections from pianissimo to forte crescendo, and again diminish to thread-like pianissimo, but in all these fantastic tricks and displays of genius by the Swedish Nightingale, even to the shake, she was so closely and accurately tracked by the somnambulist that several in the room occasionally could not have told, merely by hearing, that there were two individuals singing—so instantaneously did she catch the notes, and so perfectly did their voices blend and accord. Next, Jenny having been told by Mr. Braid that she might be tested in some other language, this charming songstress commenced "Casta Diva," and the "Ala Bòl a mi Ritornella," in which the fidelity of the somnambulist's performance, both in words and music, was most perfect, and fully justified all Mr. Braid had alleged regarding her powers. She was also tested by Miss Lind in merely imitating language, when she gave most exact imitations; and Mr. Schwabe also tried her by some most difficult combinations of sound, which she said he knew no one was capable of imitating correctly without much practice, but the som-

nambulist imitated them correctly at once, and that whether spoken slowly or quickly. When the girl was aroused she had no recollection of anything which had been done by her, or that she had afforded such a high gratification to all present, by proving the wonderful power of imitation which are acquired by some persons during a state of artificial somnambulism; she said she merely felt somewhat out of breath, as if she had been running.

OBITUARY.—On the 12th inst., at his residence, 28, Bedford-square, George Darby Dermott, Esq., aged 45, the eminent lecturer on anatomy and surgery, deeply lamented by his beloved widow and friends.—Aug. 10th, David Barry, Esq., M.D.—Aug. 20th, Dr. Roscommon, of Peter, Stephen H. Browne, Esq., M.D., surgeon to the Infirmary and County Goal, Roscommon.—Aug. 28th, Kenrick Watson, Esq., of Stourport, F.R.C.S.

WAR-OFFICE, Sept. 10.—Hospital Staff: Peter Henry Roe, gent., to be Assist.-Surg. to the Forces.

DEATH FROM AN IMPURE ATMOSPHERE.—A long investigation took place a few days since before Mr. Baker, in Rosemary-lane, on the body of Mary White, aged two years, the child of a labourer, in Hayes-court, Rosemary-lane, whose death was the effect of fever and diarrhoea, brought on by the impure state of the atmosphere of the neighbourhood, in consequence of the want of drainage. The inquiry was called by the medical officer of the White-chapel union, in consequence of the many deaths which have taken place from a similar cause. Mr. John Liddle, surgeon of Whitechapel union, who was called to attend the deceased, said that he prescribed remedies, but they would not act as they would have done in a healthy state of the atmosphere. Witness has now six patients in that court. He has no doubt that the same effect will arise with them. Verdict: "That deceased died of diarrhoea and fever, caused by the noxious and poisonous effluvia in Hayes-court, from want of drainage." The coroner said that he would write to Lord Morpeth, and forward a copy of the depositions to his lordship.

MORTALITY TABLE.

For the Week ending Saturday, Sept. 11, 1847.

Causes of Death.	Total.	Average of 5 Summers.
ALL CAUSES.....	1040	940
SPECIFIED CAUSES...	1029	935
Zymotic (or Epidemic, Endemic, and Contagious) Diseases.....	372	226
SPORADIC DISEASES.		
Dropsy, Cancer, and other Diseases of uncertain or variable Seat.....	121	103
Diseases of the Brain, Spinal Marrow, Nerves, and Senses.....	143	157
Diseases of the Lungs, and of the other Organs of Respiration.....	175	226
Diseases of the Heart and Blood-vessels.....	32	25
Diseases of the Stomach, Liver, and other organs of Digestion.....	91	94
Diseases of the Kidneys, &c.	16	8
Childbirth, Diseases of the Uterus, &c.	9	9

THE RULES AND REGULATIONS OF EXAMINING MEDICAL BODIES IN ENGLAND, SCOTLAND, IRELAND, FRANCE, AND GERMANY.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

According to the regulations of this College, no one will be admitted as a candidate for the license, unless he shall have attained the age of six-and-twenty, and shall present a certificate of good moral conduct. His medical education must comprise Anatomy, the Theory and Practice of Medicine, Forensic Medicine, Chemistry, Materia Medica, Natural History (principally Botany), Midwifery, and the principles of Surgery, and must extend over the period of five years. Practical Medicine must be studied for three years in a hospital containing at least 100 beds, and having a complete staff of physicians and surgeons. Those who have studied abroad, in addition to giving proof of five years' medical education according to the usual course of study, are required to present testimonials of a twelve-month's medical practice at any hospital in Great Britain, having the qualifications as above.

No one will be admitted as a Licentiate (*Permissus*) who is accustomed to use any secret medicine or nostrum in the treatment of disease, unless previously to his first examination he make known to the president and censors its composition and the manner in which it is employed. Every candidate must undergo three examinations, each conducted at different times, before the president and censors in *comitia minora*. The first examination comprises Physiology, the second Pathology, and the third Therapeutics. After the first examination, the president may inquire of the candidate where he studied polite literature and the principles of science, and what honours he has obtained, whether in Philosophy, Arts, or Medicine, in order that the answers may be recorded by the registrar. The candidate will also be examined in Greek works on medicine, to wit, Hippocrates, Galen, or Aretæus. Passages from the aphorisms of Hippocrates or Galen will be brought forward during the first examination; and during the second and third, passages from Hippocrates, Galen, or Aretæus, which must be translated into Latin, and illustrated with a brief commentary. If the candidate be deficient in his knowledge of Greek, he will be required to translate parts of Celsus or Sydenham, or some other Latin work on Medicine, into English. The examinations are conducted in Latin or English at the pleasure of the censors.

Whenever a candidate has passed the prescribed examinations, and has been approved, he will be proposed at the next *comitium majus* (a meeting of the fellows at large) to be admitted as a licentiate; and, if the majority present consent, he will be admitted accordingly. If, however, the candidate be rejected, he cannot present himself for re-examination for a twelvemonth.

Before the licentiate is admitted, he is required to plight his faith to the College according to a formula, pronounced by the President before the Fellows assembled in *comitia minora*.

If any one holding the license of the College practice Pharmacy afterwards, or engage in such a change, he is liable to expulsion; and any person practising medicine in London, or within seven miles thereof, without having previously obtained the collegiate license, is to be admonished by letter to cease his practice, until after he has passed the required examinations; and if he continues to practice, despite this admonition, then *legibus regnabimus erit*.

Persons who have attained their fortieth year, seeking to become Licentiates of the College, but whose medical education is not altogether in accordance with the regulations already stated, must present testimonials of professional knowledge and good moral conduct, and if these are satisfactory, they will be admitted to examination, the same as for licentiates in general.

The old regulation restricting the fellowship, as a matter of right, to the graduates of Oxford, Cambridge, and Trinity College, was repealed in the latter part of 1835; and after Easter, 1836, all candidates were declared to be admissible as licentiates only, from which class, when duly qualified, a certain number are to be annually elected fellows in *comitia majora*. The advantage derived by graduates of the English universities, and by the Irish graduate who possesses an *ad eundem* degree from an English university, is, that they are eligible a year after they have obtained the license; the Scotch graduate, being M.A. or B.A., five years later. If the latter does not possess any degree in arts, his eligibility for the fellowship does not occur until after the lapse of seven years. The Irish graduates who do not possess an *ad eundem* degree are not eligible for two years after they are licensed. The president and censors propose the candidates for the fellowship, but the *comitia majora* may reject the proposition, and choose their nominees. The election is by ballot.

The president of the college is *ex-officio* president of the Vaccine Board, a trustee of the British and Hunterian Museums, physician to the Queen, and an elector to the Tancred scholarships. The college has the power of recommending a physician to Christ Church, St. Thomas's, and St. Bartholomew's Hospitals; but if the recommendation succeed, it is then required to pay an annual stipend of £30 or £40 to the physician. The college also appoints the professor of botany to the University of Oxford.

The examinations for the license are conducted by the president and censors. The periods at which they take place are Michaelmas, Christmas, Easter, and in the month of June. The new censors are elected on the 24th of June, when the Harveian oration is delivered. The lectures are delivered in the early part of the year. There are about fifteen delivered: three Galstonian, three Croonian, and three Lumslean, so called from the names of those who left endowments to the college for the purpose; and six lectures on *Materia Medica*. The museum and library are attached to the institution, to which the fellows and, by permission, their friends have access.

The president may each year propose one candidate for the license, he being an M.D., but not otherwise eligible; and he may also name annually a licentiate of ten years' standing for the fellowship. The fellows have also the power of proposing a licentiate of seven years' standing, who is thirty-six years of age, for the fellowship; but this has been done so rarely as to be, in fact, obsolete.

The college fees are £66. 17s. for the license; the fellow pays in addition £1. 1s. annually to the collegiate fund.

If any fellow or licentiate can be proved, to the satisfaction of the president and censors, to have wilfully accused any other fellow or licentiate of professional ignorance, &c., unless it be before the legally-constituted judges, he shall be fined £4 for the first offence, and £8 for the

second; if he offend a third time, if a fellow, he shall be expelled, and if a licentiate, fined £10. This last fine is to be enforced every time afterwards the licentiate shall so offend. If any fellow or licentiate shall offer his professional assistance to any patient whom he shall know to be under the care of another physician, whether fellow or licentiate, without having been asked in writing by the patient professionally, he shall be fined £5.

If any fellow be proved to have made any arrangement with a druggist to share with him the proceeds of his prescriptions, he shall be expelled; if a licentiate have entered into a similar arrangement, he shall be fined £10 every time he shall so offend.

Every physician, whether fellow or licentiate, shall attend to each patient which he visits the day of the month, the names of the sick men, and his own initials. When a consultation takes place, it is to be carried on with modesty, not in the presence of the sick, and if any difference of opinion occurs, it is to be settled with prudence and moderation, so that it may not be noticed by the patient or the friends, but if required, should be mentioned by the senior medical attendant. Whoever infringes these regulations will be fined £5 by the president and censors.

No fellow or licentiate may consult, in London, or within seven miles thereof, with a physician who does not belong to the college, under a penalty of £5 fine.

All fines are to be paid immediately. The president and court of the college have the power of committing individuals concerning their authority to Newgate. This power has been exercised by the court, but not of late years.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. Regulations for Candidates for the Fellowship of the Royal College of Surgeons of England.

1. That every candidate for the fellowship, whether a member of the college or not, shall produce certificates satisfactory to the court of examiners,—

That he is twenty-five years of age. That he is (if found qualified upon his examination) a fit and proper person to be admitted to the fellowship, and the certificate of which shall be signed by three fellows.

That he has attained a competent knowledge of the Greek, Latin, and French languages, and of the elements of mathematics.

That he has been engaged for six years in the acquirement of professional knowledge in recognised hospitals or schools of surgery and medicine within the United Kingdom of Great Britain and Ireland, or in foreign countries; and that three of such years at least have been passed in one or more of such recognised hospitals or schools in London.

That he has attended the surgical practice of a recognised hospital or hospitals during four years, and the medical practice of a recognised hospital or hospitals for one year.

That he has studied anatomy and physiology by attendance on lectures and demonstrations, and by dissections, during three winter sessions of not less than six months each, at one or more recognised school or schools.

That he has attended lectures on the theory and practice of medicine, and on clinical medicine, and also on the theory and practice of surgery, and on clinical surgery, during two sessions of six months each, at one or more recognised school or schools.

That he has attended one course of lectures on each of the following subjects, viz.: chemistry, materia medica, midwifery, medical jurisprudence, and comparative anatomy, at one or more recognised school or schools. And that he has served the office of house-surgeon or dresser in a recognised hospital in the United Kingdom. Every such candidate (except in the case and instances hereinafter provided for to the contrary) shall also present for examination clinical reports, with observations of six or more surgical cases taken by himself at a recognised hospital or recognised hospitals within the United Kingdom,

with sufficient certificates of their authenticity and genuineness, and shall leave such reports at the college.

3. That as to any candidate who shall have taken the degree of bachelor of arts in an English university, and shall produce satisfactory evidence thereof, it shall, instead of the certificate or certificates that he has been engaged for six years in the acquirement of the professional knowledge as before mentioned, be sufficient for him to produce a satisfactory certificate or certificates that he has been engaged for five years in the acquirement of professional knowledge in recognised hospitals and schools of surgery and medicine within the United Kingdom, or in foreign countries, and that three of such years at least have been passed in one or more of the recognised hospitals or schools of London; and that it shall not be necessary for any candidate having so taken the degree of bachelor of arts to produce any certificate of his having acquired a competent knowledge of the Greek, Latin, and French languages, and of the elements of mathematics.

4. That upon the 1st day of January, 1850, or at any earlier period which may be thought proper, the council shall, under such regulations, and for such time or period, as to them shall seem proper (but always subject to removal at the pleasure of the council), appoint three persons, and being, or not being, and either all, or in part, members of the college, as the council shall think proper for the purpose of examining persons intending to become candidates for the fellowship, and required to be examined in the Greek, Latin, and French languages, and in the elements of mathematics; and the said council, from time to time after the first appointment of such persons for such purpose as aforesaid, and as often as shall be necessary, or to the said council shall seem proper in their behalf, shall appoint such other person and persons as to them shall seem fit and proper to succeed or supply the place or places of any person or persons previously appointed for such purpose; and that, from and after the first appointment of any such persons for the purpose of making such examination as aforesaid, no certificate of a candidate having competent knowledge of the Greek, Latin, and French languages, and of the elements of mathematics, shall be received or allowed by the court of examiners, except the certificate or certificates of the persons for the time being so appointed as aforesaid.

5. That all members of the college, future as well as present, shall be entitled to be admitted to the examination for the fellowship according to the foregoing by-laws and ordinances.

6. That any person who shall have been a member of the college on the 11th day of September, 1841, shall, after the expiration of eight years from the date of his diploma, also be entitled to be admitted to the examination for the fellowship upon the production of a certificate signed by three fellows that he has been eight years in the practice of the profession of surgery, and that he is a fit and proper person to be admitted a fellow, if upon examination he shall be found qualified.

7. That any person who shall have become a member of the college after the said 14th day of September, 1841, shall, after the expiration of twelve years from the date of the diploma, also be entitled to be admitted to the examination for the fellowship upon the production of a certificate signed by three fellows that he has been for twelve years in the practice of the profession of surgery, and that he is a fit and proper person to be admitted a fellow, if upon examination he shall be found qualified, and also if he have not taken the degree of Bachelor of Arts in an English university, of a certificate or certificates that he has a competent knowledge of the Greek, Latin, and French languages, and of the elements of mathematics.

EXAMINATION OF CANDIDATES FOR THE FELLOWSHIP.

1. The examination for the fellowship shall be held three times in the year, at or within such

periods as the council shall from time to time determine.

2. Each candidate shall be examined on two days, either successive or at such an interval as the Court of Examiners may appoint.

3. The subjects for the first day's examination shall be anatomy and physiology; those of the second, pathology, therapeutics, and surgery.

4. The time allowed for examination each day shall be from ten o'clock in the forenoon until five o'clock in the afternoon.

5. The examination shall be conducted in the following manner. Each candidate shall, upon going in for examination, have delivered to him a written or printed copy of such questions as shall have been previously determined upon by the Court of Examiners, and to which questions he shall give written answers, and which answers shall be considered by the Court of Examiners.

The court may, however, if they should think fit, interrogate any candidate on any matters connected with the questions or answers. In the anatomical examination, the candidate shall also perform dissections and operations on the dead body in the presence of the Court of Examiners, or of such members thereof as may be deputed by the court to superintend the same. Candidates whose qualification shall be found insufficient shall not be allowed to present themselves a second time until after the expiration of one year from their first examination.

The Court of Examiners shall report in writing to the council the names of such persons as they shall have found upon examination to be qualified for the fellowship.

* * * Members of the college will pay ten guineas besides charges for status, and non-members thirty guineas.

Regulations of the Council respecting the Professional Education of Candidates for the Diploma who commenced their Studies before the year 1838.

1. Candidates will be required to bring proof—1. Of being twenty-two years of age. 2. Of having been engaged five years in the acquirement of professional knowledge. 3. Of having studied anatomy and physiology, by attendance on lectures and demonstrations, and by dissections, during two anatomical seasons. 4. Of having attended at least two courses of lectures on surgery, delivered in two distinct periods or seasons; each course to comprise not less than sixty lectures. 5. Of having attended lectures on the practice of physic, on chemistry, and on midwifery, during six months, comprising not less than sixty lectures respectively, and on botany and materia medica during three months. 6. Of having attended during twelve months the surgical practice of a recognised hospital in London, Dublin, Edinburgh, Glasgow, or Aberdeen; or for six months in any one of such hospitals, and twelve months in any recognised provincial hospital.

Regulations of the Council respecting the Professional Education of Candidates for the Diploma after the termination of the Session 1839-1840.

1. Candidates will be required to bring proof—

1. Of being not less than twenty-one years of age. 2. Of having been engaged in the acquirement of professional knowledge for not less than four years, three of which shall have been passed in a recognised school or schools of surgery; three months of vacation being allowed in each year, and in the event of absence or absences from such school or schools during the said term of three years (exclusive of the vacations), the full term being completed in a subsequent year. 3. Of having studied anatomy and physiology, by attendance on lectures and demonstrations, and by dissections, during two anatomical seasons. 4. Of having attended at least two courses of lectures on surgery, delivered in two distinct periods or winter seasons of six months, each course to comprise not less than seventy lectures. 5. Of having attended one course of lectures on the practice of physic, and one on chemistry, during six winter months, comprising not less than seventy lectures respectively; one course on materia medica with medical botany,

during six months, and one on midwifery during six months, each comprising not less than sixty lectures; and at least twenty-five lectures on medical jurisprudence. Certificates of attendance on these lectures during the summer season will be received, provided they are equally divided over a period of four months. The lectures on medical jurisprudence may be delivered three days in the week. 6. Of having attended, during twenty-one months, the surgical practice of a recognised hospital in London, Dublin, Edinburgh, Glasgow, or Aberdeen; or for twelve months in any one of such hospitals, and twelve months in any recognised provincial hospital. 7. Of having attended the medical practice of a hospital or dispensary during six months.

II. Members and licentiates in surgery of any legally-constituted college of surgeons in the United Kingdom, and graduates in surgery of any university, requiring residence to obtain degrees, will be admitted for examination on producing their diploma, license, or degree, together with proofs of being twenty-two years of age, and of having been occupied five years in the acquirement of professional knowledge.

N.B. Certificates will not be recognised from any hospital unless the surgeons thereto, or a majority of them, be members of one of the legally-constituted colleges of surgeons in the United Kingdom; nor from any school of anatomy, physiology, or midwifery, unless the respective teachers be members of some legally-constituted college of physicians or surgeons in the United Kingdom; nor from any school of surgery, unless the respective teachers be members of some legally-constituted college of surgeons in the United Kingdom. Certificates will not be received on more than two branches of science from one and the same lecturer; but anatomy and physiology—demonstrations and dissections—materia medica and botany—will be respectively considered as one branch of science.

Regulations of the Council respecting the Professional Education of Candidates for the Diploma. August 15, 1843.

1. Candidates will be required, in addition to a certificate of being not less than twenty-one years of age, to bring proof—1. Of having been engaged in the acquirement of professional knowledge for not less than four years; during which period they must have studied practical pharmacy for six months, and have attended one year on the practice of surgery at a recognised hospital or hospitals in the United Kingdom;—three months being allowed for a vacation in each year. (By a resolution of the council, on the 7th of November, 1839, no provincial hospital will, in future, be recognised by the college which contains fewer than 100 patients, and no metropolitan hospital which contains fewer than 150 patients.) 2. Of having studied anatomy and physiology, by attendance on lectures and demonstrations, and by dissections, during three winter seasons, of not less than six months each. 3. Of having attended at least two courses of lectures on the principles and practice of surgery, delivered in two distinct periods or seasons; and one course on each of the following subjects—viz., the practice of physic, chemistry, and materia medica, and midwifery, with practical instruction.

Certificates will not be received unless the candidate have duly registered his tickets. The other regulations are virtually the same as before.

These three forms of regulations are in force respecting candidates for the diploma, according to the period when they commenced their studies. Fee for the diploma (including stamp), £22; for an articulated student (allowed in the diploma fee), £10. 10s.; for a certificate of having had the diploma, £5. 5s.; for being enfranchised, £10. 10s.; a certificate for a surgeon in the Royal Navy, or East India Company's service (allowed in diploma fee), £5. 5s.; for an assistant surgeon, £2. 2s.; for a candidate calling a special court, £5. 5s.

Studentships in Anatomy.—Three studentships

in human and comparative anatomy have been instituted by the college, to be held by each student for the term of three years, at a salary of one hundred pounds per annum. And with the view of promoting the objects of the college, in the institution of these studentships, the Commander-in-Chief of the army, the Lords Commissioners of the Admiralty, and the Court of Directors of the East India Company, have placed at the disposal of the president and the council an assistant-surgeoncy of each service, once in three years, for such of the said students as may be considered worthy of the honourable distinctions. 2. Candidates to be members of the college, under twenty-six years of age. 3. The council will determine annually whether one or more of such appointments shall take place during the current year; and will notify its resolution by public advertisement. 4. The appointment is made in the month of June, or as soon after as possible. 5. The students are subject to such duties and restrictions as the council shall from time to time direct; and in case of misconduct are liable to dismissal. 6. Candidates are required to transmit to the secretary, on or before the 1st of May, their applications for the appointment, together with certificates of general good character, and of fair acquirements in general learning, signed by two qualified members of the medical profession. 7. A meeting of the museum committee will be held as soon after the 1st of May as conveniently may be, at which the applications of the persons offering themselves will be examined, and, if approved, the applicants will be admitted as candidates. 8. The museum committee will determine the merits of the several candidates, and report to the council which, in their opinion, possess the highest merit. 9. The students are required to attend in the museum daily (Sundays excepted) from ten till four o'clock, and are under the immediate direction of the museum committee.

The museum is opened to visitors on Monday, Tuesday, Wednesday, and Thursday, from 12 till 4, except during the month of September; on Friday, to gentlemen for studying in it; and on Saturday, from 10 till 1, to gentlemen desirous of comparing specimens with those in the museum. The library is open to members and students of the college, and visitors having tickets of admission, daily (Sundays excepted), from the 1st of October to the 1st of April, from 10 till 4; and from the 1st of April to the 1st of September, from 10 till half-past 5.

The lectures at the college by the professors are delivered in the spring of the year, the Hunterian oration on the 14th of February.

APOTHECARIES' HALL.

Every candidate for a certificate of qualification to practise as an apothecary will be required to produce testimonials:—1. Of having served an apprenticeship of not less than five years to an apothecary. 2. Of having attained the full age twenty-one years. 3. Of good moral conduct. 4. And of having pursued a course of medical study, in conformity with the regulations of the court.

Course of Study.

Every candidate whose attendance on lectures commenced on or after the 1st of October, 1835, must have attended the following lectures and medical practice during not less than three winter and two summer sessions: each winter session to consist of not less than six months, and to commence not sooner than the 1st nor later than the 16th of October; and each summer session to extend from the 1st of May to the 31st of July.

First Winter Session.—Chemistry; Anatomy and Physiology; Anatomical Demonstrations; Materia Medica and Therapeutics; this course may be divided into two parts of fifty lectures, each one of which may be attended in the summer.

First Summer Session.—Botany and Vegetable Physiology; either before or after the first Winter Session.

Second Winter Session.—Anatomy and Physiology; Anatomical Demonstrations; Dissections; Principles and Practice of Medicine.

Second Summer Session.—Forensic Medicine. **Third Winter Session.**—Dissections; Principles and Practice of Medicine.

Midwifery, and the Diseases of Women and Children, two courses in separate sessions, and subsequent to the termination of the first Winter Session. Practical Midwifery, at any time after the conclusion of the first course of Midwifery Lectures.

Medical Practice during the full term of eighteen months, from or after the commencement of the second Winter Session; twelve months at a recognised hospital, and six months at a recognised hospital, or a recognised dispensary; in connection with the hospital attendance, a course of Clinical Lectures and instruction in Morbid Anatomy will be required.

The sessional course of instruction in each subject of study is to consist of not less than the following number of lectures:—One hundred on Chemistry—One hundred on Materia Medica and Therapeutics—One hundred on the Principles and Practice of Medicine—Sixty on Midwifery and the Diseases of Women and Children—Fifty on Botany and Vegetable Physiology.

Every examination of an hour's duration will be deemed equivalent to a lecture. The lectures required in each course must be given on separate days. The lectures on Anatomy and Physiology, and the Anatomical Demonstrations, must be in conformity with the regulations of the Royal College of Surgeons of London in every respect. Students must also produce testimonials of attendance on a course of Clinical Lectures; of instruction in Practical Chemistry and Morbid Anatomy; and of having dissected the whole of the human body once at least; without which testimonials the candidate cannot be admitted to examination.

The above course of study may be extended over a longer period than three winter and two summer sessions, provided the lectures and medical practice are attended in the prescribed order and in the required sessions.

Those gentlemen whose attendance on lectures commenced before the 1st of October, 1835, will be allowed to complete their studies in conformity with the previous regulations of the court.

No member of the court of examiners will be recognised as a lecturer on any branch of Medical Science. The court will not recognise any lecturer unless he lectures in connection with a recognised medical school; nor will they recognise a lecturer on more than two branches of medical science; nor until he has produced very satisfactory testimonials of his attainments in the science he purposes to teach, and of his ability as a teacher thereof; from at least two persons of acknowledged talents and distinguished acquirements in the particular branch of science in question; and also given a public course of lectures on the subject he proposes to teach; but if, after such preliminary course, the lecturer shall be recognised, certificates of attendance on that course will be received.

Satisfactory assurance must also be given that the teacher is in possession of the means requisite for the full illustration of his lectures, viz., that he has, if lecturing—On Chemistry, a laboratory and competent apparatus—On Materia Medica, a museum sufficiently extensive—On Botany, a hortus siccus, plates or drawings, and recent plants—On Midwifery, a museum, and such appointments in a public institution as may afford the means of practical instruction to the pupils.

No hospital will be recognised by the court unless:—1. It contain at least one hundred beds. 2. It be under the care of two or more physicians, members of the Royal College of Physicians of London, or graduated doctors of medicine of a British university. 3. The physicians give a regular course of clinical lectures and instruction in Morbid Anatomy. 4. The apothecary be legally qualified, either by having been in practice prior to the 1st of August, 1815, or by having received a certificate of qualification from this court. No dispensary will be recognised by the court unless it be situated in some town where there is

a recognised medical school, and be under the care of at least two physicians and an apothecary legally qualified. No medical practice will be available unless it be attended in conformity with the course of study prescribed for pupils.

Names of Gentlemen having the Care of the Registers.

Birmingham: W. Sands Cox, Esq., Lecturer on Anatomy. **Bristol:** Dr. Wallis, and Henry Clark, Esq., Lecturers on Anatomy. **Hull:** Edward Wallis, Esq., Lecturer on Anatomy. **Leeds:** Thomas Nunneley, Esq., Lecturer on Anatomy. **Liverpool:** Dr. Malins, Medical Jurisprudence. **Manchester:** Thomas Turner, Esq., Anatomy. **Newcastle:** William Dawson, Esq., Midwifery. **Sheffield:** W. Jackson, Esq., Anatomy. **York:** John Hopps, Esq., Anatomy.

Registration of Testimonials.

All testimonials must be given on a printed schedule (a), with which students will be supplied in London, at this hall.

In Edinburgh, Messrs. M'Lachlan and Stewart's, booksellers.

In Dublin, at Messrs. Hodges and Smith's, booksellers.

In the provincial towns, from the gentlemen who keep the registers of the Medical Schools.

All students in London are required personally to register the several classes for which they have taken tickets; and those only will be considered as complying with the regulations of the court whose names and classes in the register correspond with their schedules.

Tickets of admission to Lectures and Medical Practice must be registered in the months of October and May; but no ticket will be registered unless it be dated within seven days of the commencement of the course; and certificates of attendance must be registered in the months of April and August. Due notice of the days and hours of such registration will be given from time to time.

The court also require students of the Provincial Medical Schools to register their names in their own handwriting, with the registrar of each respective school, within the first twenty-one days of October, and first fourteen days of May; and to register their certificates of having duly attended Lectures on Medical Practice within fourteen days of the completion of such attendance.

The registrars are requested to furnish the court of examiners with a copy of each registration immediately after its close, as those students only will be admitted to examination whose registrations have been duly communicated to the court.

Examination.

Every person intending to offer himself for examination must give notice in writing to the clerk of the society on or before the Monday previously to the day of examination, and must at the same time deposit all the required testimonials at the office of the headle, where attendance is given every day, except Sunday, from ten until four o'clock.

The examination of the candidate for a certificate of qualification to practise as an apothecary will be as follows:—

(b) In translating portions of the first four books of "Celsus de Medicina," and of the first twenty-three chapters of Gregory's "Compendium Medicinæ Theoreticæ."

In Physicians' Prescriptions, and the "Pharmacopœia Londinensis."

In Chemistry.

In Materia Medica and Therapeutics.

In Botany.

In Anatomy and Physiology.

In the Principles and Practice of Medicine, in—

(a) It is particularly requested that the lecturer himself will fill up the blanks in the schedule, specifying the mode of attendance, applied at the time of their first registration:—

(b) By an order of the court, in future the Latin language will form part of the general examination.

cluding Midwifery and the Diseases of Children.

The examination of the candidate for a certificate of qualification to act as assistant to an apothecary, in compounding and dispensing medicines, will be as follows:—

In translating Physicians' Prescriptions, and the "Pharmacopœia Londinensis,"
In Pharmacy and Materia Medica.

By the 22nd section of the Act of Parliament, no rejected candidate for a certificate to practise as an apothecary can be re-examined until the expiration of six months from his former examination; and no rejected candidate as an assistant until the expiration of three months.

The court meet in the hall every Thursday, where candidates are required to attend at a quarter before four o'clock.

The act directs the following sums to be paid for certificates:—

For London, and within ten miles thereof, ten guineas.

For all other parts of England and Wales, six guineas.

Persons having paid the latter sum become entitled to practise in London, and within ten miles thereof, by paying four guineas in addition.

For an assistant's certificate, two guineas.

By an order of the Court.

HENRY BLATCH, Sec.

Apothecaries' Hall, Aug., 1845.

UNIVERSITY OF OXFORD.

Full term is understood to begin on the first day of the week after the congregation has been held; so that, if the congregation be held on the Monday, the Sunday after is considered the first day of full term.

According to the lately-altered statute respecting medical degrees, a candidate for the degree of Bachelor in Medicine, before he can be admitted to examination for that degree, must have kept four whole years, or sixteen terms, in the university, in like manner as is required by candidates for a degree in arts (a); must have passed the examination for the degree of bachelor in arts; and subsequently to that examination must have studied medicine during three whole years, or twelve terms; and must also have completed seven years, or twenty-eight terms, from his matriculation.

The medical examination takes place only once in the course of the year—namely, in the second week of full Trinity term, commencing usually on the second Tuesday after Trinity Sunday. The candidates are examined, principally "vivâ voce," but partly in writing, in the theory and practice of medicine, in anatomy, physiology, pathology, and materia medica; and also in chemistry and botany, as far as they elucidate the art of medicine. He is required to be conversant with the entire works of Aretæus and Celsus; the aphorisms and epidemics of Hippocrates; and that portion of Galen's writings entitled "De Usâ Partium;" in two, at least, of which authors, the statute directs that the examiners fall not to test the candidate's attainments. He must send, fourteen days before the day of examination, certificates of three years' attendance on the medical practice of a hospital, with the usual lectures.

Certificates are required for two courses of anatomy and physiology, each extending from October till the following April or May; two courses on the theory and practice of medicine, each course of the same extent; one course in materia medica; one course in botany; one course in chemistry, provided the course extend through the usual winter session, otherwise two courses will be required.

A candidate for the degree of doctor in medicine must have pursued the study of medicine during three years after he has graduated as bachelor in medicine, and must give at least a fortnight's previous notice of his intention to the professor of medicine, at the same time sub-

(a) That is, he must be of sixteen terms' standing, and have actually resided in the university twelve terms.

mitting to approbation a subject for a medical dissertation, which dissertation must be read in the public schools of the university within a few days of taking the degree of M.D., and delivered to the professor immediately after it has been read. No graduate in medicine from another university can be incorporated at Oxford unless he produce testimonials by which it may clearly appear that he has kept by residence terms equal to those required to be so kept in this university; he has completed all the exercises prescribed by the university from which he migrates for the degree of bachelor of arts; and shall have previously undergone the medical examination above described; and shall have fulfilled all the other conditions of the present statute. The fees for a bachelor of medicine are £23; for a doctor in medicine, £40.

The University of Oxford is in possession of the Bodleian library (librarian, B. Bandinel, M.A.); of the Radcliffe library (librarian, Dr. Kidd); of the Ashmolean museum (keeper, P. B. Duncan, M.A.); and of the botanic gardens, founded by the Earl of Derby in 1632. All these are open to students under certain restrictions.

Radcliffe Travelling Fellows.—Dr. Radcliffe left by will an endowment of £600 per annum, to be paid to two persons, to be chosen out of the University of Oxford, when they are M.A., entered on the study of physic, for their maintenance for ten years, and no longer, the half of which time, at least, they are to travel in parts beyond sea, for their better improvement. In case of vacancy by death, or at the expiration of the ten years, a new election is to take place within six months.

UNIVERSITY OF CAMBRIDGE.

Dr. Haviland delivers a course of fifty lectures on the principles of pathology and the practice of physic; £5. 5s. first course, afterwards gratis. The professor of chemistry delivers thirty lectures, on the general principles of that science, during Lent term, and twenty lectures, principally on organic chemistry, during Easter term. Lectures on experimental philosophy, to illustrate the laws of hydrostatics, pneumatics, and optics, with particular reference to the mathematical theories of light and sound, are delivered in Easter term. About fifty lectures on anatomy, by Dr. Clark, are delivered in Michaelmas and Lent terms. The terms of attendance are £5. 5s. for each of two courses, afterwards gratis. The people have the opportunity of dissecting in private. Botanical lectures are given during the Easter term, with herborising excursions occasionally. Professor Willis's lectures on natural and experimental philosophy are during the Michaelmas term; the subjects being statics, dynamics, and mechanism, with their practical illustrations: first course, £3. 3s.; second, £2. 2s.; afterwards gratis. The Downing professor of physic delivers a course of fifty lectures on some medical subject. A certificate of attendance is required of persons proceeding to the degree of M.B. Lectures are also delivered on crystallography and mineralogy during the Lent term. Addenbrooke's Hospital, which is connected with the university, is recognised by the Colleges of Physicians and Surgeons, and by Apothecaries' Hall. It contains 100 beds, and has a department reserved for cases of midwifery.

A student, before he can become a bachelor of physic, must have entered on his sixth year, computed from the date of his first admission at the university, have resided nine terms, and have passed the previous examination.

A bachelor of arts may become a bachelor of physic after having entered on his sixth year, computed from the date of his first admission at the university, provided that one year at least has intervened between his final determination in arts and his admission to the degree of bachelor of physic.

The exercises for this degree are one act and one opponyony.

Candidates for the degree of bachelor of physic must, in addition to the examination by the

regius professor of physic, be examined by the professors of anatomy, chemistry, and botany, and by the Downing professor of medicine. This examination must not take place before the fifth year after admission. They must have diligently attended the lectures of the regius professor of physic for two terms, and must bring to him certificates of examination by the above professors, and of attendance on their lectures, in case the course of lectures of the professor of botany consist of not less than twenty lectures, and the courses of lectures of the professors of anatomy and chemistry, and of the Downing professor of medicine, of not less than fifty lectures each. They must also deliver to the regius professor of physic certificates of having been diligently employed in attendance on medical lectures, and the practice of some well-known hospital, for two years, or for as long a time as they have been absent from the university during their undergraduateship. Fee, £10. 10s.

A license *ad practicandum in medicina* may be granted to a bachelor of physic in the term subsequent to that in which he has taken the degree, or a master of arts of two years' standing.

Candidates for a license *ad practicandum in medicina*, being previously bachelors of physic, are required to produce to the regius professor of physic certificates of their having attended on hospital practice for three years, exclusive of the nine terms which they kept by residence for the degree of bachelor of physic, and of their having attended lectures on the following subjects:—practice of physic and pathology, anatomy and physiology, chemistry, botany, medical jurisprudence, materia medica and pharmacy, principles of surgery, principles of midwifery, practical anatomy, for two seasons.

Candidates for a license *ad practicandum in medicina*, being previously masters of arts, are required to bring satisfactory evidence to the regius professor of physic of their having been employed in the study of physic for five years after they became bachelors of arts; and to produce to him certificates of their having attended on hospital practice for three of the said five years, and of their having attended lectures on the subjects before mentioned.

Every candidate for a license *ad practicandum in medicina* is required to pass an examination to the satisfaction of the regius professor of physic, the professor of anatomy, the Downing professor of medicine, and a doctor of physic, to be nominated by the vice-chancellor, and approved by the senate, at the first congregation after the 10th of October in each year.

There are two such examinations in every year; one in the week immediately preceding that in which the division of the Michaelmas term falls; the other in the week immediately preceding that in which the division of the Easter term falls.

A candidate for a license *ad practicandum in medicina*, being previously bachelor of physic, cannot be examined for the said license until the examination which shall occur next but one after his having passed the examination required for the degree of bachelor of Physic. Fee, £11. 6s.

M.D.—The degree of doctor of physic is granted to a bachelor of physic of five years' or to a master of arts of seven years' standing.

The exercises for this degree are two acts and one opponyony.

Every candidate for the degree of doctor of physic, who has not previously obtained a license *ad practicandum in medicina*, is required to produce to the regius professor of physic the same certificates, and pass the same examination, as are required in the case of candidates for a license *ad practicandum in medicina*. Fee, £11. 12s.

The university possesses an anatomical museum, to which has been added the valuable collection of the late Dr. Macartney, the Fitzwillian, Mesman, Mineralogy, and Geological Museums, an extensive botanic garden, and the university library. To all these the students have access.

UNIVERSITY OF EDINBURGH. (1682.)

Matriculation.—Every student in the faculties

of arts, law, and medicine, before entering with any professor, must produce a matriculation ticket for the ensuing session. Tickets will be issued at the matriculation office, in the colleges every lawful day, from ten till three. Enrolment in the general album is the only legal record of attendance in the university.

Library.—The library will be open for the purpose of giving out books to students, either on loan or for reference, in the hall appropriated for that purpose, every lawful day during the winter session, from ten a.m. till four p.m., except on Saturdays, when it will be shut at one precisely.

Every student applying for books must present to the librarian his matriculation ticket for the session, with the ticket of at least one professor. Every book taken out must be returned within a fortnight, uninjured.

Fee for each course, £4. 4s. For graduation, £25.

STATUTES OF THE UNIVERSITY OF EDINBURGH RELATIVE TO THE DEGREE OF M.D.

Sect. I. No one shall be admitted to the examinations for the degree of doctor of medicine who has not been engaged in medical study for four years, during at least six months of each, either in the University of Edinburgh, or in some other university where the degree of M.D. is given; unless, in addition to three *Anni Medici* in a university, he has attended, during at least six winter months, the medical or surgical practice of a general hospital, which accommodates at least eighty patients, and during the same period a course of practical economy, in which case three years of university study shall be admitted.

Sect. II. No one shall be admitted to the examinations for the degree of doctor who has not given sufficient evidence—1. That he has studied, once at least, each of the following departments of medical science, under professors of medicine, in this or some other university, as already defined—viz.:—

During Courses of Six Months.—Anatomy, chemistry, materia medica and pharmacy, institutes of medicine, practice of medicine, surgery, midwifery and the diseases peculiar to women and children, general pathology, practical anatomy (unless it has been attended in the year of extra-academical study allowed by Sect. I.).

During Courses of Six Months, or Two Courses of Three Months.—Clinical medicine, that is, the treatment of patients in a public hospital, under a professor of medicine, by whom lectures on the cases are given.

During Courses of at least Three Months.—

1. Clinical surgery, medical jurisprudence, botany, natural history, including zoology
2. That in each year of his academical studies in medicine he has attended at least two of the six months' courses of lectures above specified, or one of these and two of the three months' courses.
3. That, besides the course of clinical medicine already prescribed, he has attended, for at least six months of another year, the medical or surgical practice of a general hospital either at Edinburgh or elsewhere, which accommodates not fewer than eighty patients.
4. That he has attended for at least six months, by apprenticeship or otherwise, the art of compounding and dispensing drugs at the laboratory of a hospital, dispensary, member of a surgical college or faculty, licentiate of the London or Dublin Society of Apothecaries, or a professional chemist or druggist.
5. That he has attended for at least six months, by apprenticeship or otherwise, the out practice of a hospital, or the practice of a dispensary, or that of a physician, surgeon, or member of the London or Dublin Society of Apothecaries.

Sect. III. No one shall obtain the degree of doctor who has not studied, in the manner already prescribed, for at least one year previously to his graduation, in the University of Edinburgh.

Sect. IV. Every candidate for the degree in medicine must deliver, before the 24th of March of the year in which he proposes to graduate, to

the Dean of the Faculty of Medicine—1. A declaration, in his own handwriting, that he is twenty-one years of age, or will be so before the day of graduation, and that he will not be then under articles of apprenticeship to any surgeon or other master. 2. A statement of his studies, as well in literature and philosophy as in medicine, accompanied with proper certificates. 3. A medical dissertation, composed by himself, in Latin or English, to be perused by a professor, and subject to his approval.

Sect. V. Before a candidate be examined in medicine, the medical faculty shall ascertain, by examination, that he possesses a competent knowledge of the Latin language.

Sect. VI. If the faculty be satisfied on this point, they shall proceed to examine him, either *visu voce* or in writing.—1. On anatomy, chemistry, botany, institutes of medicine, and natural history bearing chiefly on zoology; and 2. On materia medica, pathology, practice of medicine, surgery, midwifery, and medical jurisprudence.

Sect. VII. Students who profess themselves ready to submit to an examination on the first division of these subjects, at the end of the third year of their studies, shall be admitted to it at that time.

Sect. VIII. If any one, at these private examinations, be found unqualified for the degree, he must study, for another year, two of the subjects prescribed in Section II., under professors of medicine, in this or in some other university, as above defined, before he can be admitted to another examination.

Sect. IX. Should he be approved of, he will be allowed, but not required, to print his thesis; and, if printed, forty copies of it must be delivered, before the 25th day of July, to the Dean of the Medical Faculty.

Sect. X. If the candidate have satisfied the medical faculty, the dean shall lay the proceedings before the *Senatus Academicus*, by whose authority the candidate shall be summoned, on the 31st of July, to defend his thesis; and, finally, the senate think fit, he shall be admitted, on the first lawful day of August, to the degree of doctor.

Sect. XI. The *Senatus Academicus*, on the day here appointed, shall assemble, at ten o'clock a.m., for the purpose of conferring the degree; and no candidate, unless a sufficient reason be assigned, shall absent himself, on pain of being refused his degree for that year.

Sect. XII. Candidates for graduation shall be required to produce evidence of their having conformed to those regulations which were in force at the time they commenced their medical studies in a university.

ROYAL COLLEGE OF PHYSICIANS, EDINBURGH.

The members of the college are respectively entitled Ordinary Fellows, Non resident Ordinary Fellows, and Licentiate's.

Ordinary Fellows.—No one shall be elected an ordinary fellow of the college till he has obtained the degree of doctor of medicine.

Every motion for the election of a fellow shall be made, at a quarterly meeting, by one of the fellows present, seconded by another, and determined by ballot—a majority of three-fourths being necessary to carry it in the affirmative.

No physician residing in Edinburgh shall be proposed for a resident fellowship till he has been a licentiate for nine months, or, in case of his not being a licentiate, till nine months after his petition to be admitted a resident fellow shall have been presented, unless an urgent reason be assigned; in this case, he may be proposed even on the same day on which he becomes a licentiate, or at any other quarterly meeting, or at a meeting specially called for the purpose, if this proposal shall be agreed to by every member present.

No fellow shall engage himself to any candidate before the ballot; nor shall he reveal to any person in what manner he did ballot, under the pain of being considered as one who has broken his faith and honour to the college.

No fellow shall take his seat in the college till the quarterly meeting after that on which he is

elected, intimation to attend being then sent to him by the clerk.

The fellows shall be placed on the roll according to the dates of their admissions; and, when two or more fellows are admitted on the same day, they shall be entered on the roll according to the dates of their diplomas; and, if their diplomas be of the same date, they shall be enrolled according to their ages.

Every fellow before taking his seat in the college must sign a promissory engagement.

It shall be in the power of any fellow of the college to move that a candidate having a foreign degree be admitted without a previous examination; and, if the motion shall be seconded, it shall be determined by ballot at next quarterly meeting, a majority of three-fourths of the fellows present being necessary to carry it.

If an examination shall take place, it shall consist of three trials: the first by two fellows appointed by the college, on any part of medicine; the second, by two other fellows, on two aphorisms of Hippocrates; and the third, by two other fellows, on two medical cases. All these trials shall be in the presence of the college, and in the Latin language.

Non-resident Fellows.—No physician residing in Edinburgh is eligible for a non-resident fellowship.

The mode of election of a non-resident fellow is the same as that of a resident fellow; and the laws regarding examination, in the case of a foreign degree, also apply to him.

Fees.—The fee to be paid by a resident licentiate is £100.

The fee to be paid by a non-resident licentiate is £55.

The fees are exclusive of any tax payable to government now existing, or which may hereafter be imposed.

ROYAL COLLEGE OF SURGEONS, EDINBURGH. (1505.)

Regulation for Fellows.—The candidate is required—To present an essay on some surgical subject, which, if approved of, he must print for circulation among the fellows. He must then undergo three examinations—1. On anatomy and surgery; 2. On chemistry, materia medica, &c.; 3. On the essay he has written. If these are satisfactorily passed, he is admitted to the fellowship. Fee, £250; to apprentices of fellows, £100.

School of Medicine.—Every candidate for a surgical diploma must have followed the course of study, to be specified afterwards, in a university; or at the seat of an established school of medicine, as defined below; or in a provincial school, specially recognised by the college.

Under the title, established school of medicine, are comprehended all places in this kingdom where diplomas in surgery are granted, and such foreign schools as are acknowledged by the constituted authorities of the countries in which they exist.

The extent and period of study allowed to be gone through at a provincial school will be regulated by the means and facility of study which the college receive evidence of its affording; but the lectures delivered at a provincial school will be held as qualifying for only one year's course of study, unless specially recognised for more.

Qualifications of Teachers.—The following classes of persons shall be entitled to give lectures, which may be attended as part of the course of study:—1. In the universities of Great Britain and Ireland, and in University College and King's College, London, the professors of these institutions. 2. In Edinburgh, resident fellows of the Royal College of Physicians of Edinburgh, and fellows of the Royal College of Surgeons of Edinburgh. 3. In London, fellows and licentiates of the Royal College of Physicians of London, and members of the Royal College of Surgeons of London, whose status as teachers has been admitted by that college. 4. In Dublin, fellows of King's and Queen's College of Physicians in Ireland, and members of the Royal College of Surgeons in Ireland. 5. In Glasgow,

members of the Faculty of Physicians and Surgeons of that city. 6. In recognised provincial schools, teachers whose status as such has been admitted by the college, on special application. 7. In any of the above schools teachers who, having acquired a status as such in one of the four established schools, in conformity with the above regulations, shall have been subsequently admitted, on application to the college, to the enjoyment of the same privileges in another school. (a)

The following branches of instruction may be conjoined:—Anatomy and practical anatomy, chemistry and practical chemistry, practice of medicine and clinical medicine, practice of surgery and clinical surgery, mathematics and mechanical philosophy; and, for the present, clinical medicine or clinical surgery may be taught in conjunction with any one of the other courses of education prescribed in the curriculum, by a physician or surgeon qualified according to the regulations of the college, and attached to a public hospital of the size which these regulations prescribe.

Course of Study.—Preliminary Instruction.—Every candidate for the diploma of the Royal College must, either previously to or during his medical education, have received regular instruction in the elements of mathematics; and must have subsequently attended a course of mechanical philosophy of at least three months' duration, and of not fewer than sixty lectures.

Professional Instruction.—The candidate must have been engaged in attending the following separate and distinct courses of lectures during a period of not less than twenty-seven months, in which must have been included three winter sessions of six months' duration each: Anatomy, two courses of six months each. Practical anatomy, twelve months. Chemistry, one course of six months. Practical chemistry (the number of pupils in each class being limited to twenty-five), one course of three months. Materia medica and pharmacy, one course of six months. Practical pharmacy, one course of six months. Institutions of medicine, or physiology, one course of six months. Practice of medicine, one course of six months. Clinical medicine, one course of six months, or two courses of three months each, during the period of his attendance at the hospital where they are delivered. Principles and practice of surgery, two courses of six months each, or principles and practice of surgery and military surgery, one course of six months each. Clinical surgery, one course of six months, or two courses of three months each, during the period of his attendance at the hospital where they are delivered. Midwifery and diseases of women and children, one course of three months. Medical jurisprudence, one course of three months.

The six months' courses delivered in Edinburgh must consist of not fewer than 110 lectures, with the exception of clinical medicine, clinical surgery, and military surgery. The three months' courses must consist of not fewer than sixty lectures. Two London courses of three months each on any of the above subjects will be taken as equivalent to one six months' course.

The candidate must also have attended for twenty-one months a public general hospital containing at least eighty beds.

Fees payable by Candidates.—For a diploma, ordinary candidates pay the sum of £7. 5s. (Apprentices of fellows of the Royal College,

(a) The only lectures expected from this law are those on mechanical philosophy and on chemistry. The former may be professors in universities, lecturers in public institutions, or teachers; specially recognised by the college; and the latter may be persons not medical, if recognised by the college on special application, in conformity with a resolution of the college on the 25th October, 1838. In all cases of special recognitions, proof of capability, and of the applicant possessing the requisite apparatus for illustrating his lectures will be required.

bound for the freedom, pay 25s.; their other apprentices pay £2. 16s. 6d. Assistant-surgeons in the navy, having previously obtained certificates from the college, pay £2. 11s. 6d. Surgeons in the navy, having obtained certificates from the college, pay 16s. 6d.)

For the certificate of qualification to act as assistant-surgeon in the navy, candidates not having paid for any previous qualification pay £4. 19s. 6d.

For the certificate of qualification to act as full surgeon in the navy, assistant-surgeons who have already obtained certificates from the college pay £3. 18s. 6d., and those who have previously obtained the diploma of the college pay £2. 17s. 6d.

UNIVERSITY OF GLASGOW.—REGULATIONS REGARDING DEGREES IN MEDICINE AND SURGERY TO CANDIDATES ENTERING THE UNIVERSITY IN, OR SUBSEQUENT TO, 1839-40.

Medicine.—Every candidate for a medical degree must lodge with the clerk of senate—

1. A certificate of moral character, by two respectable persons, with evidence of having attained the age of twenty-one.

2. Evidence of having attended, for four years, a university in which medicine is regularly taught, or medical lectures delivered in London or Dublin; and at least one year of the four must be spent at the University of Glasgow. In each year he must have attended at least two courses of lectures of six months' duration; but if he shall spend one year only at the University of Glasgow, then he must attend three courses of lectures delivered there, two of them, at least, being of six months' duration.

3. Certificates of having attended one or more courses of lectures on the following subjects, each course, except forensic medicine and botany, being of six months' duration; if of less extent, then two courses shall be deemed equivalent to one of six months:—Anatomy and physiology; chemistry; the theory or institutes of medicine; practice of medicine; materia medica and pharmacy; midwifery; surgery; forensic medicine; botany(a); anatomical dissections; and two years' practice of a general hospital, containing eighty beds, and in which the student must spend at least one-half of the period of attendance in the physicians' wards. Neither hospital attendance nor anatomical dissections shall be considered as equivalent to a course of lectures.

4. Each candidate must lodge with the clerk of senate, with the above certificates, a schedule of his course of study, properly filled up, together with an English essay on some medical subject chosen by himself, two months before the time of graduation—that is, on or before the 1st of March, or the 10th of June, yearly, otherwise he cannot be admitted for examination till the following term. All tickets of attendance lodged by candidates must be certified, not excepting those of the current session; but the certified botanical tickets of the current session shall not be received until the 1st of April.

5. No student entered in any medical class later than the 1st of December, without special permission of the senate. And it is strictly required of every candidate for graduation that he produce evidence of his name having been enrolled in the library-book, on or before that day, as well as an express certificate of his regular attendance by each professor on whose lectures he attends. In order, further, to ensure attendance, all students must inscribe their names, once a fortnight, in a register kept for the purpose, stating the lectures, &c., which they attend.

6. Every candidate shall prove that he has a competent knowledge of Latin, and shall undergo full examinations on all the subjects included in the curriculum.

Surgery.—The regulations respecting certificates of age and moral character are the same as those under the head of degrees in medicine.

(a) No course of botany attended previously to 1839-40 is received, unless it shall have been delivered in a university.

Candidates for the degree of master of surgery shall produce evidence that they have attended medical lectures in one or other of the universities or schools already specified for four years, during which they must have attended one or more courses on the following subjects, the extent of each course, with the exception of forensic medicine, being six months, or the equivalent two courses of a shorter duration. The candidate must have attended not less than three courses of medical lectures in the University of Glasgow. In each year of his study he shall have attended at least two or more courses of lectures, of six months' duration, on anatomy, surgery, chemistry, theory or institutes of medicine, practice of medicine, midwifery, materia medica and pharmacy, forensic medicine, anatomical dissections, and two years' practice of a general hospital, in which the student must attend one-half of the prescribed period in the surgical wards, and the other half in the medical.

The regulations as to lodging certificates of attendance, and an essay in English, and as to the candidate's knowledge of Latin, are the same as under the head of medical degrees, only the essay is to be on a surgical subject. The days of graduation are the last Wednesday of April and the first Wednesday of August.

Fee to the library, &c., for the degree of M.D. £15 0 0

Duty on stamp for ditto 10 3 0

£25 3 0

Fee for the degree of Chirurgiæ Magister £10 10 0

N.B. Candidates for degrees who attended classes in the University of Glasgow previously to 1839-40 admitted to examination, according to the regulations which existed at the time when they began to study medicine.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

Regulations for the Surgical Diploma.—The faculty recommend that candidates should attend elementary courses of study in mathematics and natural philosophy. These branches, however, are not imperative. Every candidate's knowledge in Latin should be tested at his examination, by being required to construe some part of Gregory's "Conspectus Medicinæ Theoreticæ."

Curriculum.—Anatomy, two courses of six months. Practical anatomy, one course of six months; enacted 7th June, 1830. Surgery, two courses of six months. Chemistry, one course of six months. Practical chemistry, one course of three months; enacted 8th November, 1831. Theory of medicine, one course of six months. Practice of medicine, one course of six months. Materia medica, one course of six months. Midwifery, one course of six months. Clinical medicine, one course of six months; enacted 7th June, 1830. Clinical surgery, one course of six months; enacted 7th June, 1830. Medical jurisprudence and police, one course of six months; enacted 4th April, 1811. Botany, one course of three months; enacted 3rd February, 1834. A public hospital, eighteen months; enacted 3rd February, 1834. A surgeon's or apothecary's shop, six months; enacted 3rd February, 1834.

The above lectures must have been delivered by professors or lecturers in a university; or by resident members of the Royal Colleges of Physicians or Surgeons respectively of London, Edinburgh, or Dublin; or by means of the faculty. Every candidate must have been employed in the above course of studies for four winter sessions, or for three winter sessions and two summer sessions, so that the whole period of attendance shall not be less than three years complete. An essay, the subject to be fixed by the examiners, to be written by the candidate, in his own handwriting; and no essay to be submitted for a shorter period than twenty-four hours. Specimens of bones, or other anatomical or surgical preparations, or specimens from the materia medica, shall be used at the discretion of the examiners. The fee of seven guineas shall be deposited with the president previous to the examination, and at the same time satisfactory

documents shall be produced that the above curriculum of education has been duly completed by certified attendance.

N.B. Those branches, whose dates are specified, are not required by those students who commenced their studies anterior to these enactments. The commencement of education is ascertained by the date of the first ticket.

The fees for the diploma are £7. 7s. The president, visitor, collector, box-masters, and seal-keeper, form, along with the assistant-examiners, the examining court. The diploma of the faculty is recognised by all the licensing bodies in the three kingdoms, and by the poor-law commissioners in England and Ireland.

KING'S COLLEGE, ABERDEEN.—REGULATIONS TO BE OBSERVED IN GRANTING DEGREES IN MEDICINE AT KING'S COLLEGE.

All candidates for the degree of M.D. must be of the age of twenty-one years, and must produce satisfactory certificates of moral character, and exhibit the diploma of A.M. from some university.

All candidates, with the exceptions mentioned below, must have been engaged in the study of medicine for at least four years, one of which must be passed in Aberdeen, and must produce evidence of having attended, in some recognised school of medicine, the following courses of lectures:—Six months' courses: anatomy, two courses; chemistry, one course; materia medica, one course; surgery, one course; institutes of medicine and physiology, one course; practice of medicine, one course; midwifery, one course. Three months' courses: dissections, two courses; practical chemistry, one course; medical jurisprudence, one course; clinical surgery, one course; botany, one course; clinical medicine, two courses.

In addition to the above, the candidate must have attended for two years the wards of a hospital containing 100 beds; and, during three months, a shop or dispensary for the compound ing of medicine.

The preceding regulations are strictly enforced in the case of all students who shall commence their medical studies at a period subsequent to 1st October, 1840. But gentlemen who possess a license or diploma from any of the royal colleges of physicians or surgeons, and who have been engaged for at least five years in the practice of medicine, may be admitted to examination on producing their license or diploma, along with satisfactory evidence of sufficient preliminary education and of good moral character.

Previously to examination each candidate must lodge with the secretary £26 5s. 6d., the same to be returned to him should he not obtain his degree.

Degrees in medicine are conferred at two stated periods annually—viz., at the end of April, and at the end of July.

REGULATIONS FOR GRANTING MEDICAL DEGREES IN MARINCHAL COLLEGE AND UNIVERSITY, ABERDEEN.

Curriculum.—Four years of attendance on medical classes, of which one year may be passed at any recognised medical school; but three, at least, must be passed in a university, including one, at least, in this university. The attendance in each year to embrace not fewer than two medical classes of six months each; or one of six months, with two of three months each. But it will be held equivalent to one of four years of such attendance in a university—1st, in a master of arts, to have attended one medical class while passing through the curriculum of arts; or, 2ndly, in any student, to have attended a medical class, in each of two years, along with classes in the curriculum of arts. The university attendance to include the following eight classes, each for a course of six months:—Anatomy, practical anatomy, chemistry, materia medica, institutes of medicine, surgery, practice of medicine, midwifery, and the following three classes, each for a course of three months:—botany, practical chemistry, medical jurisprudence.

Eighteen months of attendance on the medical

and surgical practice of a hospital containing not fewer than eighty beds, along with attendance for six months on lectures on clinical medicine, and for three months on lectures on clinical surgery.

Six months of compounding and dispensing medicines in the laboratory of a hospital, or of a public dispensary, or of a licensed general practitioner, or of a regular dispensing druggist.

Exemption to Practitioners.—It will be held equivalent to the curriculum prescribed in the three foregoing regulations to have obtained, upon examination, a diploma or a license, in medicine or in surgery, from a university or other authority established by law within the United Kingdom, and to have subsequently attended medical classes in this university during one winter session.

Examinations.—The examination terms to be two in each year—the first to commence on the 20th of April, if a Wednesday, but if not, on the first Wednesday thereafter; the second on the 13th of October, if a Wednesday, but if not, on the first Wednesday thereafter.

Every candidate to undergo at least three separate professional examinations—the first, pharmaceutical; the second, surgical; the third, medical: to be conducted partly in writing, as well as *visu voce*, and partly by demonstration. The first to include chemistry, botany, materia medica, pharmacy, and the doctrines of physics relating to specific gravities, to gases and vapours, and to climate. The second to include anatomy, institutes of medicine, surgery, and the doctrines of chemistry and physics illustrative of animal structure and function. The third to include the practice of medicine, midwifery, and medical jurisprudence.

Every candidate not a master of arts must undergo a preliminary examination on the Latin language (the book to be used being *Celsus de Medicina*), and on the etymology of such terms in the medical sciences as are derived from the Latin and the Greek.

Any candidate that so desires shall be admitted to each one, or to any two, of his three professional examinations, at different terms; but not to the first examination until the beginning of his third year of medical classes; nor to the second until the end of his third year; nor to the third until the end of his fourth year, and until he be twenty-one years of age; nor shall a greater interval than eighteen months be allowed between two successive professional examinations without a full renewal of the previous one or two. The preliminary examination must be passed at the same term as the first professional examination.

In order to be received for examination, certificates must have been lodged with the professor of medicine on the first day of the month of the examination term, showing that the candidate is of the required age, that he is of good moral character, and that he has passed through the requisite course of professional education. Along with such certificates must be lodged a schedule, filled up in his own handwriting, containing a list of them, and specifying such additional branches of education, professional and general, as he may have studied.

UNIVERSITY OF ST. ANDREW'S. (1412).—REGULATIONS FOR GRANTING MEDICAL DEGREES.

The candidate must produce evidence of unexceptionable moral character, and before being admitted to examination must subscribe a declaration that he is twenty-one years of age.

The candidate must have had a liberal classical education, and, if he be not in the possession of the degree of A.M., must be ready to undergo an examination as to his proficiency in the Latin language.

The candidate must produce certificates that he has regularly attended lectures delivered by professors in some university, or by resident fellows of the Royal Colleges of Physicians or Surgeons of London, Edinburgh, Glasgow, Aberdeen, or Dublin, for at least four complete winter sessions, or three winter and three summer sessions, on the following branches:—1, anatomy, two courses

of six months each; 2, practical anatomy, twelve months; 3, theory of medicine, or physiology, one course of six months; 4, chemistry, one course of six months; 5, practical chemistry, one course of three months; 6, materia medica and pharmacy, one course of six months; 7, surgery, one course of six months; 8, clinical medicine, one course of six months; 9, practice of medicine, one course of six months; 10, clinical surgery, one course of six months; 11, midwifery and diseases of women and children, one course of three months; 12, an apprenticeship, or six months' attendance in the shop of an apothecary, or in the laboratory of a public hospital or dispensary; 13, attendance at a public hospital, containing not less than eighty beds, for at least eighteen months.

These regulations will be invariably observed, except when the candidates are possessed of a surgeon's diploma or license from the Colleges of London, Edinburgh, or Dublin, or the Faculty of Physicians and Surgeons of Glasgow, or a license from the Apothecaries' Company, in which case they have merely to present such diploma or license previous to their examination for M.D.

UNIVERSITY OF DUBLIN (TRINITY COLLEGE). 1591.

Chancellor, his Majesty the King of Hanover; Vice-Chancellor, his Grace the Lord Primate of Ireland; Proctor, Dr. Sudleir.

The days of graduation are, Shrove Tuesday, and the first Tuesday in July. The degree of bachelor of medicine may be obtained in two modes:—

1. Graduates in arts can obtain the degree at any of the half-yearly periods of graduation, provided the requisite medical education and examination shall have been accomplished. Fee for entrance, £16; fees for study in arts during four years, £7. 10s. each half year; fees for graduation in arts, £8. 17s. 6d.

2. Candidates are admissible to the degree of M.B., without previous graduation in arts, at the end of five years from the July following the Hilary examination of the first undergraduate year, provided the usual education and examinations in arts of the first two years of the undergraduate course shall have been completed, as also the medical education and examinations, as in the case of other candidates. Fees for two years' study in arts (besides the usual entrance payment of £16) are £7. 10s. each half year. The graduation fees for the degree of bachelor of medicine are £11. 15s. The standing of the first undergraduate year may be obtained by attending the October examination of that year if the student has entered not later than the first Monday of the July of the same year, and has completed the payments due since the ordinary period of entrance in the preceding November. The medical education of a bachelor of medicine comprises attendance on the following courses of lectures in the school of physic established by act of Parliament, provided that one, and not more than three, of the courses which begin in November be attended during each of four sessions. Three of these courses, at the discretion of the candidate, may be attended at the University of Edinburgh. The courses are on—anatomy and surgery, chemistry, botany, materia medica and pharmacy, institutes of medicine, practice of medicine, midwifery (by the professor to the College of Physicians), clinical lectures at Sir Patrick Dun's Hospital, during at least one session (six months), as delivered by the professors in the school of physic; the attendance on such clinical lectures by the professors to be extended to three additional months of a summer session commencing in May. This regulation to affect all students commencing their medical studies after 17th July, 1841, and to be in lieu of attendance on the hospital from 1st May to the 1st November following. The fees for attendance on the clinical lectures are £3. 3s. to the professors for each three months' attendance, and (provided the student be of two years' standing in the university) £2. 3s. to the treasurer of the hospital for the first year, with a proportionate

sum for any longer period. The fee for each of the other courses is £4. 4s. The examinations are conducted by the regius professors of physic of the university, the six professors of the school of physic, and the professor of midwifery to the King and Queen's College of Physicians. No further examination is requisite for the degree of doctor of medicine, which may be taken at the expiration of three years from having taken the degree of M.B., provided the candidate shall have graduated in arts. The fees for the degree of doctor of medicine are £22. The degrees are publicly conferred by the vice-chancellor, in the senate or congregation of the university.

COLLEGE TERMS.

Hilary begins January 10, ends March 25.

Trinity " April 15, " June 30.

Michaelmas, October 10, " December 20.

KING AND QUEEN'S COLLEGE OF PHYSICIANS
IN IRELAND.

Qualifications of Candidates for License.—Candidates must produce evidence of having been engaged in the study of medicine for four years, and of having attended two at least of the required courses in each year. Candidates, except those who have taken a medical degree prior to 1840, must produce certificates of attendance on one or more courses of lectures on the following subjects, each course being of six months' duration, with the exception of botany and forensic medicine, which must include at least fifty lectures:—Anatomy and physiology, chemistry, materia medica and pharmacy, botany, institutes of medicine, practice of medicine, and surgery.

of medicine are required to have been delivered by the respective professors of the school of physic in Dublin, or in a university. The lectures on surgery are required to have been delivered on at least three days in the week, during four months, by a professor of surgery in a university or college of physicians or surgeons in the United Kingdom, or by the surgeon of a medico-chirurgical hospital recognised by the college. These lectures must not form a part of a course of lectures on anatomy. The lectures on midwifery are required to have been delivered by a professor of midwifery in a university or college of physicians or surgeons in the United Kingdom, or by the master of the Lying-in Hospital, Dublin. The lectures on medical jurisprudence are required to have been delivered by a professor in a university or college of physicians or surgeons in the United Kingdom. Certificates must also be produced of six months' attendance on anatomical demonstrations and dissections, and of at least two years' hospital practice; one year in the hospital of the school of physic in Dublin or Edinburgh, the other in any recognised medico-chirurgical hospital. The certificates must include attendance on the entire practice of the hospital, and on all the clinical lectures delivered in the hospital during such attendance. Candidates who have taken a medical degree in a university shall be admitted to examination upon such degree alone. Every candidate for license, except those who have taken a medical degree prior to 1810, is examined on two separate days: on the first day on anatomy and physiology, chemistry, botany, materia medica, and pharmacy; and on the second day, on acute and chronic diseases, midwifery, and non-naturals, and on the translating of one or more of the following books from the original Greek, viz.: Hippocrates, Aretæus, and Galen. Graduates in medicine are only required to undergo the second day's examination. The examinations, which are public, are conducted in the English language; but every candidate, except graduates in arts at Oxford, Cambridge, or Dublin, is required to translate medical cases from the English into the Latin language, before he is admitted to examination as to his professional acquirements. Fee for license, £30. The license of this college is equivalent to a medical degree, and it confers privilege which a degree does not.

The fellows are chosen from the licentiates of three years' standing; they are required by statute (40 Geo. III., cap. 84, sect. 42) to have taken the degree of M.D. in one of the universities of Dublin, Oxford, or Cambridge; or to have taken the degree of A.B. in one of these universities, and to have received the medical education requisite for obtaining the license, for which a degree in medicine is not necessary. Fee to the college on election to the fellowship, £20, with an additional stamp duty of £25.

The act of Parliament provides that these qualifications may be dispensed with whenever, at any time, the number of fellows is reduced to six.

The college has the power of conferring the honorary fellowship on any of its own licentiates who have not the statutable qualifications; on such of its fellows as resign or vacate the fellowship; and on such eminent medical men, not licentiates, as it may wish to distinguish by its approbation.

ROYAL COLLEGE OF SURGEONS IN IRELAND. (1784—1828.)

By-laws respecting the Registry of Pupils.—Every person requiring to be registered as a pupil on the college books shall be so registered, if he shall have laid before the court of censors the following documents, viz.:—

Provided he be an apprentice, and shall have paid any apprentice fee:—1. A receipt showing he has lodged, to the credit of the president and for the use of the college, in the Bank of Ireland, the registry fee of ten guineas. 2. A receipt showing that the member or licentiate to whom he is indentured has lodged a similar sum of ten guineas. 3. A declaration, subscribed by the member or licentiate to whom he is indentured, stating that he has really and *bonâ fide* received the usual fee of one hundred and fifty guineas, or value to that amount. 4. His indenture of apprenticeship, duly executed, and bearing the requisite stamp.

Provided he be an apprentice, and shall not have paid an apprentice fee, he shall lay before the court: 1. A declaration, subscribed by the member or licentiate to whom he is indentured, that he has not received, or that he does not expect to receive, any apprentice fee. 2. A receipt, showing that he has lodged, to the credit of the president and for the use of the college, in the Bank of Ireland, the sum of fifty guineas. 3. His indenture of apprenticeship, regularly executed and registered.

Provided he be an apprentice, and be the son, brother, or nephew of the member or licentiate to whom he is indentured, or the son of some other member or licentiate of the college, and shall not have paid an apprentice fee, he shall lay before the court:—1. A declaration, subscribed by the member or licentiate to whom he is indentured, that he has not received, or that he does not expect to receive, any apprentice fee. 2. A receipt, showing that he has lodged, to the credit of the president and for the use of the college, in the Bank of Ireland, the sum of ten guineas.

Provided he shall not be an apprentice to a member or licentiate of the college:—1. A receipt, showing that he has lodged, to the credit of the president and for the use of the college, in the Bank of Ireland, the registry fee of ten guineas.

By-laws relating to Education and the Qualification of Candidates for Letters Testimonial.—Every registered pupil or apprentice shall be admitted to an examination for letters testimonial, if he shall have proved and showed that his professional education has been, in all respects, conformable and agreeable to the provisions and enactments of the by-laws and rules of the college, and shall have laid before the court the following documents:—1. A receipt, showing that he has lodged, as a registry-fee, the sum of ten guineas in the Bank of Ireland, to the credit of the president and for the use of the college, previously to his being admitted to any examination. 2. A receipt, showing that he has lodged a sum of twenty guineas in the Bank of Ireland, to the credit of the president, and for the use

of the college, previous to his final examination for letters testimonials. 3. A certificate, signed by the president or vice-president, and two of the court of censors, that he has passed an examination as to his acquaintance with the Greek and Latin languages. 4. Certificates, showing that he has been engaged in the study of his profession for not less than four years, three of which shall have been passed in attendance on lectures or hospitals, during the winter sessions, in Dublin, London, Edinburgh, or Glasgow. 5. Certificates of attendance on a surgical hospital where clinical instruction is constantly given, containing fifty patients at least, for a period of not less than twenty-four months. 6. Certificates of attendance on the medical practice of a recognised hospital or dispensary, where clinical instruction is constantly given during twelve months. 7. Certificates of attendance on three courses of lectures on anatomy and physiology, three courses of lectures on the theory and practice of surgery, and of the performance of three courses of dissections, accompanied by demonstrations; also certificates of attendance on two courses of lectures on chemistry, or one course of lectures on general, and one on practical, chemistry; one course of lectures on materia medica; one course of lectures on the practice of medicine; one course of lectures on midwifery, and one course of lectures on medical jurisprudence. 8. A thesis, essay, or dissertation, in Latin or English, or any of the following subjects:—Anatomy, physiology, surgery, the practice of medicine, chemistry, materia medica, midwifery, or medical jurisprudence; or, in the place of such dissertation, a series of cases collected in the hospital in which the candidate has attended, illustrated by comments or observations.

A candidate, being a registered pupil, shall be allowed to pass the first of the two days' examination above mentioned, on anatomy and physiology, on laying before the court of censors the following documents:—1. A receipt, showing that he has lodged a sum of ten guineas in the Bank of Ireland, to the credit of the president and for the use of the college. 2. Certificates, showing that he has been engaged in the study of his profession for not less than three winter sessions in Dublin, London, Edinburgh, or Glasgow. 3. Certificates of attendance on three courses of lectures on anatomy and physiology, and of the performance of three courses of dissections, accompanied by demonstrations; such candidate not being admissible to the second day's, or the final, examination, on the other subjects above specified, until he shall have lodged a further sum of ten guineas in the Bank of Ireland, to the credit of the president and for the use of the college, and shall have laid before the court of censors all the documents enumerated in the by-laws relative to "qualifications for the letters testimonial." Notice of every examination for letters testimonial is posted in the hall, and the secretary also, by regular summonses, gives notice of such examination to the members resident in Dublin. The examination takes place in the presence of such members and licentiates as choose to attend. The candidate is examined on two several days in anatomy and physiology, on the practice of medicine and surgery, and on any other branch of medical science, and shall perform such surgical operations or dissections, and explain such anatomical preparations, as the court may require.

Fee for letters testimonial or diploma, £31. 10s.; and for admission as member (which takes place by ballot after three years' standing as a licentiate, and confers corporate rights) £31. 10s.

APOTHECARIES' HALL OF IRELAND. 1791.

Laws regarding the Education of Apothecaries.—Every candidate must undergo two separate examinations—one for the certificate of apprentice, the other for the license to practise.

Every candidate for the certificate of apprentice must have attained the age of fifteen years, and will be examined in the following books:—The works of Sallust; the first six books of the Æneid of Virgil; the Satires and Epistles of

Horace; the Greek Testament; the Dialogues of Lucian; the first four books of Homer's Iliad the first six books of Telemachus, or the History of Charles the Twelfth (in French); the first two books of Euclid; and algebra—to simple equations.

Every candidate for the license to practise an apothecary must lay before the court the following documents:—1. The certificate of apprenticeship. 2. The indenture of apprenticeship, enrolled according to the act of Parliament and bearing the certificate of the licentiate apothecary to whom he has been indentured, that he is of good moral character, and has fulfilled the period of his apprenticeship. 3. Certificates duly signed that he has diligently attended at least one course of lectures on each of the following subjects, delivered at the school of Apothecaries' Hall, or at some other school of medicine recognised by the court (the order of the study here laid down is recommended for the guidance of students):—Chemistry, anatomy, and physiology, six months; practical chemistry and botany, three months; materia medica, demonstrations, and dissections, theory and practice of physic, surgery, midwifery and the diseases of women and children, six months; medical jurisprudence, three months.

A certificate of twelve months' attendance on the entire practice of a medico-chirurgical hospital, recognised by the court, containing not less than fifty beds, and where clinical instruction is regularly given.

Also, a certificate of having assisted in at least thirty cases of midwifery practice, twenty of which must be attended in a recognised hospital.

The examination for the license to practise as an apothecary will be as follows:—In translating and explaining the process of the British pharmacopœias and extemporaneous prescriptions; in chemistry and general physics; in materia medica and therapeutics; in natural history and medical botany; in anatomy and physiology; in the theory and practice of medicine; in midwifery; in medical jurisprudence.

The examination for the license to act as assistant to an apothecary in compounding and dispensing medicine will be confined to the following subjects:—To translate the Dublin Pharmacopœia, and extemporaneous prescriptions; pharmacy, botany, materia medica, and mechanical philosophy.

The candidate for the assistant's license may present himself for examination at the termination of five years' apprenticeship.

The court of examiners sit every Friday, at two o'clock, and proceed with the examination of candidates in the order in which their names appear on the list.

• A rejected candidate cannot be readmitted to examination until the expiration of six months, and, after a second rejection, can appeal to be examined by the King and Queen's College of Physicians.

All lecturers are required to furnish the court of examiners with a list of such gentlemen as have taken out admission tickets on or before the 1st day of January; also a similar list of those who have obtained certificates of having attended their respective courses, with the number of lectures in each course, on or before the 10th of May, annually.

REGULATIONS OF THE ARMY MEDICAL DEPARTMENT, 13, ST. JAMES'S-PLACE.

A candidate for an assistant-surgeoncy in the army is required to fill up a blank form of certificate, which may be obtained at the office by written application to the director-general, specifying by whom he is recommended, his Christian and surname at full length, with the course of study he has pursued. The candidate is, in addition, to sign and forward the following declaration:—

"I, [Christian and surname at full length], . . . years of age, a candidate for employment in the medical department of the army, do hereby attest my readiness to engage for general service, whether at home or abroad, and to proceed on duty

immediately on being gazetted. I declare my age not to exceed twenty-six years, that I am unmarried, and that I labour under no mental or constitutional disease, nor physical disability, that can interfere with the most efficient discharge of the duties of a medical officer in any climate." [Signature]

In selecting from among the candidates for the medical department of the army, a preference is given to those who can fill up all the blanks in the printed form; but the name of no gentleman can be placed on the list who does not possess the diploma of either of the colleges of surgeons of London, Edinburgh, or Dublin, and who cannot produce the following testimonials:—Eighteen months' attendance at an hospital of celebrity, where the average number of in-patients is not less than one hundred; twenty-four months' anatomy; twelve months' practical anatomy; twelve months' surgery, or (what is preferred) six months' surgery, and six months' military surgery; eight months' clinical surgery, a complete course of two or three lectures during the week; twelve months' practice of physic, or six months of practice of physic, and six months of general pathology; eight months' clinical lectures on ditto, the same as required in surgery; twelve months' chemistry; six months' practical chemistry; three months' botany; four months' materia medica; three months' practical pharmacy, or apprenticeship; five months' natural history; five months' midwifery; five months' natural philosophy.

The candidates must be unmarried, not beyond twenty-six years of age, nor under twenty-one years.

Candidates who have had a university education, and have the degree of A.B. or A.M., as well as that of M.D., will be preferred; but a liberal education, and a competent knowledge of the Greek and Latin languages, are indispensably requisite in every candidate; and the greater the attainments of the candidates in various branches of science, in addition to competent professional knowledge, the more eligible will they subsequently be deemed for promotion in the service; for selections to fill up vacancies will be guided more by reference to such acquirements than to mere seniority. Before promotion from the rank of assistant-surgeon to any higher rank, every gentleman must be prepared for such other examination as may be ordered before a board of medical officers.

Although the British schools are specified, it is to be understood that candidates who have received regular education in approved foreign universities or schools will be admitted to examination.

With the exception of practice of physic and clinical medicine by one teacher, candidates must have attended separate lectures for each branch of the science. The certificate of the teacher of practical anatomy must state the number of subjects or parts dissected by the pupil.

Certificates of lectures and attendance must be from physicians or surgeons of the recognised colleges of physicians and surgeons of the United Kingdom, or of foreign universities. A certificate that the candidate is acquainted with the art of cupping is required.

Diplomas, tickets of attendance on lectures, and certificates of regular attendance by each professor or lecturer, must be lodged at this office for examination and registry at least one week before the candidate appears for examination, and likewise certificates of moral conduct and character, one of them by a clergyman, and that of the parochial minister, are desirable. Baptismal certificates are required at the same time; if the parish register cannot be resorted to, an affidavit from one of the parents, or some person who can attest the fact, will be accepted.

All communications to be forwarded "unsealed," under cover, to "the Right Honourable the Secretary at War," with the words "Army Medical Department" at the corner.

Although, in the examination of candidates, gentlemen are expected to be qualified in every branch of study required, they are requested to

be particularly conversant in the knowledge of—1. Tropical diseases, and the diseases to which soldiers are most liable. 2. Military surgery, and works on the habits of soldiers and rules of the service. 3. "Cullen's Nosology" being that adopted in all returns and reports. 4. "Willan's Classification of Cutaneous Diseases." 5. The latest authors on the diseases of the eye. They are expected readily to translate a passage from a Greek or Latin author; to be conversant with Baillie and the later authors on morbid anatomy; with Cullen's, Mason Good's, and Gregory's "Practice of Physic," the latter giving an account of tropical diseases, and those most commonly met with in the army; with the works of Hunter, Hennen, Dr. John Thomson, Guthrie, Samuel Cooper, Millingen, Ballingall, Marshall, and Baron Larrey, on "Military Surgery," with the works of Chisholm, Bancroft, Lind, Blanc, Burnet, Johnstone, and Annesley, on "The Diseases of Warm Climates;" but Baillie's "Morbid Anatomy," Hennen's and Ballingall's "Military Surgery," 3rd edition, with his valuable work on "Medical Topography," Guthrie on "Gun-shot Wounds and on the Eye," and Gregory's "Practice of Physic," should form part of the baggage of every military surgeon.

Candidates, after passing their examination, will not have any leave of absence granted, but will be stationed at Chatham for two or three months, previously to being gazetted; and on their conduct there will depend their obtaining their commissions. The appointment of army-assistant surgeons rests with the director-general, Sir James McCrigrig, Bart., by whom the examinations are generally conducted.

NAVAL MEDICAL DEPARTMENT.—ADMIRALTY-OFFICE, SOMERSET-HOUSE.

Director-General of the Medical Department of the Navy, Sir William Burnett, M.D., Knt., K.C.H., F.R.S.

Qualifications.—The Right Hon. the Lords Commissioners of the Admiralty having been pleased to direct "that no person be admitted as an assistant-surgeon in the Royal Navy who shall not produce a certificate from one of the Royal Colleges of Surgeons of London, Edinburgh, or Dublin, of his fitness for that office; nor as a surgeon unless he shall produce a diploma or certificate from one of the said royal colleges, founded on an examination to be passed subsequently to his appointment of assistant-surgeon, as to the candidate's fitness for the situation of surgeon in the navy, and, in every case, the candidate producing such certificate or diploma shall also undergo a further examination before the director-general of the medical department of the navy, touching his qualifications in all the necessary branches and points of medicine and surgery for each of the steps in the naval medical service," the inspector-general doth hereby signify, for the information of those persons to whom it may relate, that these regulations and directions will be strictly adhered to; and further, that, previously to the admission of assistant-surgeons into the navy, it will be required that they produce proof of having received a preliminary classical education, and that they possess, in particular, a competent knowledge of Latin; also, that they are of good moral character, the certificate of which must be signed by the clergyman of the parish, or by a magistrate of the district. That they have served an apprenticeship, or have been engaged for not less than six months in practical pharmacy. That their age be not less than twenty years, nor more than twenty-four, and that they are unmarried. That they have actually attended a hospital in London, Edinburgh, Dublin, Glasgow, or Aberdeen, for two years, after the age of eighteen, in which the average number of patients is not less than 160. That they have been engaged in actual dissections of the human body twelve months; the certificates of which, from the teacher, must state the number of subjects or parts dissected by the candidate. That they have attended lectures, &c., on the following subjects, at established schools of eminence,

by physicians or surgeons of the recognised colleges of physicians or surgeons in the United Kingdom, for periods not less than hereunder stated, observing, however, that such lectures will not be admitted if the teacher shall lecture on more than one branch of science, or if the lectures on anatomy, surgery, and medicine be not attended during three distinct winter sessions of six months each:—

Anatomy (or general anatomy, twelve months; and comparative anatomy, six months), eighteen months. Surgery (or general surgery, twelve months; and military surgery, six months), eighteen months. Theory of medicine, six months. Practice of medicine, twelve months. If the lectures on the theory and practice of medicine are given in conjunction, then the period required is eighteen months (six months' lectures on pathology, if given at a university where there may be a professorship on that branch of science, will be admitted in lieu of six months' lectures on the practice of medicine). Clinical lectures, at a hospital as above (or the practice of medicine, six months; and the practice of surgery, six months), twelve months. Chemistry (or lectures on chemistry, three months; and practical chemistry, three months), six months. Materia medica, six months. Midwifery (accompanied by certificate, stating the number of midwifery cases personally attended), six months. Botany (or general botany, three months; and medical botany, three months), six months.

In addition to the tickets for the lectures, certificates must be produced from the professors, &c., by whom the lectures were given, stating the periods (in months) actually attended by the candidates. The time, also, of actual attendance at a hospital or infirmary must be certified, and the tickets as well as certificates of attendance, age, moral character, &c., must be produced by the candidate immediately on his being desired to appear for examination.

Although the above are the only qualifications which are absolutely required in candidates for the appointment of assistant-surgeon, a favourable consideration will be given to the cases of those who have obtained the degree of M.D. at either of the universities of Oxford, Cambridge, Edinburgh, Dublin, Glasgow, or London, or who, by possessing a knowledge of the diseases of the eye, and of any branch of science connected with the profession, such as medical jurisprudence, natural history, natural philosophy, &c., appear to be more peculiarly eligible for admission into the service, observing, however, that lectures on these or any other subjects cannot be admitted as compensating for any deficiency in those required by the regulations.

By the rules of the service, no assistant-surgeon can be promoted to the rank of surgeon until he shall have served three years in the former capacity, one year of which must be in a ship actually employed at sea; and it is resolved that not any diploma or certificate of examination from either of the aforesaid royal colleges shall be admitted toward the qualification for surgeon unless the diploma or certificate shall be obtained on an examination passed after a period of not less than three years' actual service, observing that no one can be admitted to an examination for surgeon unless he be a member of one of the above-named royal colleges; and whenever assistant-surgeons already in the service (whose professional education may not be in accordance with the above) obtain leave to study previously to their passing for surgeon, they will be required, on their examination, to produce testimonials of their having availed themselves of the period of leave to complete their education, agreeably to these regulations.

It is also to be observed, that candidates who may be admitted into the naval medical service, must serve in whatever ships, &c., they may be appointed to, and that, in the event of their being unable to do so from sickness, their names cannot be continued on the naval medical list, nor can they, of course, be allowed half-pay.

ORDNANCE MEDICAL DEPARTMENT. — 63, PALM STREET.

Regulation for the Admission of Candidates.—*Provisional List.*—Medical students who have completed their twentieth year, who have been well instructed in the Latin and Greek languages, the elements of mathematics and natural philosophy, and who can produce satisfactory proofs of being of good moral character, and diligent in the study of their profession and the sciences connected with it, may be entered in the provisional list of gentlemen desirous to be admitted candidates for employment in the Ordnance Medical Department. A knowledge also of modern languages, though not indispensable at the time of provisional reception, is highly desirable, and will be duly appreciated.

Candidates.—No applicant is to be received on the list of candidates before he is twenty-two, or retained on it after he is twenty-five years, of age. The age of every individual must be verified by a certificate of his baptism, if it can be procured. He must be also unmarried, and in the full enjoyment of health, both bodily and mental.

Qualifications.—Every candidate must produce a diploma from one of the colleges of surgeons of London, Edinburgh, or Dublin; and a certificate of qualification from the Society of Apothecaries in London. He must also bring proof of having diligently gone through the following branches of professional education, nearly all of which are required to enable him to take out the above-mentioned diploma and certificate:—viz., of having served an apprenticeship of five years to a surgeon and apothecary, if educated in England; but if not, qualification in the practice of medicine and pharmacy equivalent thereto;—of having attended the practice of surgery in a recognised hospital.

Hospitals, where clinical instruction is constantly given for three years, three months being allowed for a vacation in each year;—of having attended the under-mentioned lectures, &c.:—

Anatomical lectures . . .	Three anatomical seasons or sessions.
Ditto—demonstrations . . .	
Ditto—dissections . . .	
Morbid anatomy and pathology . . .	one course.
Lectures on the principles and practice of surgery, delivered in two distinct periods . . .	two courses, each comprising seventy lectures, or one course of surgery, and one of military surgery.
Natural history, or comparative anatomy . . .	one course
Chemistry	(one course of a hundred lectures.
Botany	one course.
Materia medica and therapeutics	one course of a hundred lectures.
Lectures on the principles and practice of medicine	two courses, each 100 lectures; second and third winters.
Medical practice, with clinical lectures, eighteen months, commencing the second session, viz., twelve months in a recognised hospital, and the remaining six months either in a recognised hospital or a dispensary.	
Medical jurisprudence, with toxicology	one course of fifty lectures.
Midwifery	two courses, each of lectures, second and third sessions.
Practical midwifery (not less than thirty cases)	After the conclusion of the first course of midwifery lectures, a certificate of having passed the usual examination is to be produced.

Diseases of the eye (with attendance on patients of that class.) one course.

He must produce a diploma from either of the colleges in London, Edinburgh, or Dublin, and, if not a graduated M.D. of Scotland or Ireland, after having actually passed an examination in the university where he has obtained his degree,

a certificate of qualification also from the Society of Apothecaries in London. It is likewise expected that candidates shall have attended establishments for the cure of diseases of the ear and nose, and for the treatment of patients affected with mental derangement. Certificates will not

be received on more than two branches of science, from one and the same lecturer; but anatomy and physiology, demonstrations and dissections, materia medica and botany, will be respectively considered one branch of science. In the certificates of attendance on hospital practices, and on lectures, the dates of commencement and termination are to be inserted in words at full length. The moral conduct and character of each individual must be certified by the gentlemen to whose care his education was confided; and also by a clergyman, who, if practicable, should be the incumbent or officiating minister of the parish in which the applicant usually resides. The documents above detailed are to be inspected by a board, to consist of not less than five medical officers, after which they are to examine the candidate as to his professional requirements. If his education has been chiefly medical, the examination will be principally in practical surgery; but if surgical, in the theory and practice of physic, including pharmacy. The full qualification being required on admission, a second examination is deemed unnecessary.

EAST INDIA COMPANY'S SERVICE.—REGULATIONS FOR THE ADMISSION OF MEDICAL GENTLEMEN INTO THE EAST INDIA COMPANY'S SERVICE AS ASSISTANT-SURGEONS FOR INDIA.

Age.—The assistant-surgeon must not be under twenty-two years, in proof of which he must produce an extract from the register of the parish in which he was born.

Qualifications in Surgery.—The assistant-surgeon, upon receiving a nomination, will be furnished with a letter to the Court of Examiners of the Royal College of Surgeons, to be examined in surgery, and their certificate will be deemed a satisfactory testimonial of his qualification; but should the assistant-surgeon be previously in possession of a diploma from the Royal College of Surgeons of London, or of the College of Surgeons of Dublin or Edinburgh, or of the College and University of Glasgow, or of the Faculty of Physicians and Surgeons of Glasgow, either of them will be deemed satisfactory as to his knowledge of surgery, without any further examination. He is also required to produce a certificate from the copper of a public hospital in London, of having acquired and being capable of practising with proper dexterity the art of cupping.

Qualifications in Physic.—The assistant-surgeon will also be required to pass an examination by the Company's examining physician in the practice of physic, and to produce satisfactory proof of his having attended at least two courses of lectures on the practice of physic; and, above all, that he should produce a certificate of having attended diligently the practice of the physicians at some general hospital in London for six months.

The assistant-surgeon is also required, as a condition to his appointment, to subscribe to the Military or Medical and Medical Retiring Fund at his respective presidency, and also to the Military Orphan Society, if appointed to Bengal.

The assistant-surgeon is required, by a resolution of court of the 21st of May, 1828, to apply at the office for cadets and assistant-surgeons for his orders for embarkation, and actually proceed under such orders within three months from the date of being passed and sworn before the committee for passing military appointments; he will then be furnished with an order to obtain the certificate of his appointment, signed by the secretary, for which he will pay a fee of £5 in the secretary's office.

Assistant-surgeons who shall fail to apply at the cadet department for their orders within three months from the date of their being passed and sworn before the committee, or shall not actually proceed under such orders, are considered to

have forfeited their appointments, unless special—circumstances justify the court's departure from—this regulation.

FOREIGN UNIVERSITIES.

FRANCE.

ROYAL UNIVERSITY OF FRANCE.

The faculty confers two degrees, viz., doctor in medicine, and doctor in surgery. Sixteen inscriptions, constituting four years' study, are required for either degree. The candidate must previously have obtained the degree of bachelor of letters, and bachelor of sciences; must produce a certificate of both, and the consent of his father or tutor, if under twenty-one years of age; also of good moral character from the civil authority. There are five examinations for the degree of doctor, which take place at stated periods throughout the four years. The winter session begins in November; the summer session in April. Fees for the degree, £44. Foreign graduates are required to pass five examinations, and to defend a thesis. Six years' study in a foreign university ranks as equivalent to four years' study at a French university. They are also required to present the diploma of bachelor of letters and of sciences, or else the dispensation for those degrees.

The *officiers de santé* are, by the new law, to be abolished. Englishmen desirous of attending the practice of the Hôtel Dieu at Paris can obtain admission by presenting the diploma of the College of Surgeons of London, Edinburgh, or Dublin, to the surgeons. By application at the Ecole de Médecine, a provisional card, admitting to the practice of all the other hospitals free of expense, may be obtained. Those who are desirous of graduating must inscribe their names in a book every three months; each inscription costs fifty francs, for a French diploma; if for a foreign one, thirty. The schools of medicine are open to students gratuitously, but diligent attendance is required. Subjects are very cheap, being obtained for a few shillings. This faculty possesses a library, botanic garden, dissecting-room, and a museum. The library is open every day in the week, except Thursday, from eleven to three; it is closed during September and October. The museum contains a valuable collection of anatomical preparations, specimens of natural history and materia medica, and an extensive series of surgical and other instruments. The beautiful collection of wax models of pathology has been placed in the Musée Dupuytren, at the School of Practical Medicine. The museum is open to the public every Thursday from eleven to three; to pupils on other days of the week, on presenting their cards of admission to lectures.

PRUSSIA.

There are six universities in Prussia, with faculties of medicine connected with them—namely, Berlin, Breslau, Königsberg, Göttingen, Halle, and Bonn on the Rhine. The medical studies are pursued for four years; and during that time the students attend lectures on medicine and the preliminary sciences. The bodies of criminals, and those from the neighbouring houses of correction, supply the means of dissection. The medical students intended for the service of the army are lodged and boarded at La Pépinière, at Berlin, and the poorer class of native students are made bursars. After four years the candidates are required to print and publicly defend a dissertation in the Latin language, and to undergo an examination in logic and the above-mentioned sciences, after which they receive the diploma of doctor, the fee for which is £25. This, however, does not give them the power of practising. In order to this, they must undergo the examination in surgery, medicine, and midwifery, which continues several months; and they will be required during that time to perform operations, and to treat diseases.

Hospital for Children	
Clinical Hospital	

These hospitals are free to foreigners on presenting their diplomas or passports, with their medical titles inscribed.

Government medical appointments, may be matriculated on presenting certificates of moral conduct and of the necessary scientific knowledge, particularly in philology. To be admitted to the examination *pro gradu*, they must have studied medicine for three years, and have attended lectures on anatomy, physiology, chemistry, botany, pharmacy, materia medica, pathology, therapeutics, surgery, and midwifery. Also clinical hospitals and lectures; but it does not matter at what university they have studied. The fee for the degree is about £20, and does not include the expense of printing the dissertation. It is never conferred *in absentia*.

GIESSEN.—Poor students can here obtain free admission to all the public lectures by making proper application at the university. For the other lectures the fees are from six to twelve florins for each half year, according to the number of hours occupied in the delivery. After five years, candidates are admitted to examination. The fee for the diploma is £22. 10s., which is not now granted without the candidate presenting himself *in propria persona*.

ERLANGEN.—The course of medical study at this university continues for three or four years. Foreigners, on producing certificates of lectures on anatomy, physiology, &c., no matter from what university or medical school, will be admitted to the strict examination, which will be conducted in French or English. Diploma fee, £21.

JENA.—Candidates for the degree of doctor of medicine, surgery, and midwifery, must deliver certificates of the completion of the course of medical studies, of good moral conduct, the certificates of matriculation, which cost 18s.; a

medical dissertation in Latin, and the fee for the doctorate, £23; with £3 more for the diploma in midwifery. The examination is conducted in German or Latin. The candidate must also defend his thesis in public, and afterwards print it.

ROSTOCK.—The course of medical study is continued for four or five years before graduation. The expense of graduation is about £27. Practitioners may obtain the diploma without personal attendance.

HEIDELBERG.—The examination is conducted, *visà voce*, in German, Latin, English, or French. The candidate must present certificates of attendance on anatomy, physiology, &c., and of having attended medical and surgical hospital practice. The candidate must also translate an aphorism of Hippocrates into Latin. Fee for diploma, &c., £23.

GOTTINGEN.—Regulations as Heidelberg.
KIEL.—Regulations as Giessen.

TRICKERY IN LEECHES.—The Correctional Tribunal of the Seine has just given judgment in the affair of Martin against Laurens and Vauchelet, for selling a quantity of official leeches mixed with spurious ones, to Martin. Laurens and Vauchelet were condemned to a month's imprisonment each, and a fine of 125 francs. They were also to pay 500 francs to Martin for the deception.

CHOLERA IN RUSSIA.—The cholera is making rapid advances in Russia. From Tiflis it has penetrated into the middle parts of the country. At Tagnanrock, Marianopol, and Rostof, it has made fearful ravages. At Quart, Olti, and Tehildir, although there have been several victims, it has not been so severe as in the midland parts.

TO CORRESPONDENTS.

THE MEDICAL TIMES may be procured by an order on any Newsmen or Bookseller, or it will be sent direct by post from the Office of the Medical Times to Subscribers sending by a Post-office order, directed James Angerstein, Carfax, or an order on some party in town, One Guinea IN ADVANCE, which will free them for twelve months. Half-yearly Subscription, 13s.; Quarterly, 6s. 6d.

VIATOR, Guy's, sends us a bill which was put into his hand on London-bridge. It is headed, "Mr. Wright, Surgeon-Accoucheur, 108, Blackman-street, opposite to the Dover-road." Amongst other things, Mr. Wright informs the public that, "except for midwifery, he declines to visit, unless for a fee, having had many ~~that~~ fully prove

'Three faces wears the doctor—when first sought, An angel's; a god's the second, when the cure's half wrought;

But, that cure complete, the doctor seeks his fee, The devil looks then less terrible than he!'

still medicines are requisite to mankind occasionally, as will be found upon reference to the 30th chapter of Ecclesiasticus, ver. 4, viz., 'The Lord hath created medicines out of the earth, and he is not wise who abhors them.' Truly the bill is a sad specimen of defective education.

Dr. Hector Gavin, 5, Thurlow-place, Hackney-road.—Communication received.

Mr. J. B. G. Tidman, Whittlessea, Cambridge, is thanked for the information.

Mr. J. B. Budgett, 274, Strand.—The communication, under present circumstances, inadmissible.

An Observer, R.N.—The letter must stand over till next week.

French, Higham Ferrers, will find the information he seeks in the present number.

Mr. J. Jackson, Long Clawson, Leicestershire.—The communication received.

Mr. H. Morris.—Communication received.

Mr. Buchanan.—The request will be attended to.

E. D. H., Oxford.—We are unable to say.

Chirurgus.—The fact of such methods being resorted to, in order to obtain practice, is truly humiliating to the profession. We shall have an opportunity of adverting more fully to the subject.

Justicia, Birmingham, is thanked for his communication.

Assistant-Surgeon, R.N.—Communication received.

If the writer of the article, headed "Facts in the Internal Conduct of the Royal Free Hospital," will give his name, we will publish his letter.

H. S. Ball.—The first number of the Pharmaceutical Times will be published next Saturday.

We shall make use of Mr. G.'s letter on the poor-law in our next.

Senex, who has written so largely against the injustices of a union with which he was connected, would have done the cause much more service by appending his name.

A Pupil.—The school of Mr. Dermott in Bedford-square will be continued, and, as far as we can judge, most efficiently. It deserves the more professional support, inasmuch as the widow—who has been left quite unprovided for—has an interest in its success.

Other correspondents next week.

Letters and communications have been received from Dr. Veitch, Galway; Mr. Phillips, Hales Owen; Mr. Stobo, Tortola; Mr. Abbott, Bray; Mr. Tulloch, Forfar; Mr. Costello, Portsmouth; Mr. Moyle, Clonsilla; Mr. Stephens, Northey Tydell; Mr. Mennie, Plymouth; Mr. Edwards, Liverpool; Mr. Foster, Birmingham; Mr. Brazier, Rye; Mr. Kershaw, Southport; Mr. Astley, Edinburgh; Mr. Kirkbride, Penrith; Mr. Rigg, Greenford; Mr. Halyoake, Manchester; Mr. Claby, Hitchin; Mr. Malins, Chipping Norton; Mr. Simpson, Creetown; Viator, Guy's; Dr. H. Gavin, 5, Thurlow-place, Hackney-road; Mr. J. B. G. Tidman, Whittlessea, Cambridge; Mr. J. B. Budgett, 274, Strand; French, Higham Ferrers; Mr. J. Jackson, Long Clawson; Leicestershire; An Observer, R.N.; E. S. Ball; Senex; A Pupil; Mr. H. Morris; Mr. Buchanan; E. D. H., Oxford; Chirurgus; A Constant Reader; Justicia, Birmingham; Assistant-Surgeon, R.N.

THE MEDICAL TIMES.

SATURDAY, SEPTEMBER 25, 1847.

INCOME TAX AND MEDICAL MEN.

"You'll be whipp'd for taxation one of these days."—
SHAKESPEARE.

We should very much like to know what Parliament and its tailpiece are intending to do with that precious iniquity the INCOME-TAX! If the ordinary run of events continue as oforetime, the period will shortly arrive when the walls of St. Stephen's to bear witness to the usual farcical phenomena of clept legislation. All the old pantomimic tricks within doors will come into play again with an air of freshness and pleasantry quite enchanting. Gentlemen of all ages, and of every variety of stature, both bodily and mental, will congregate together to play at dignity, and superintend the working of the machinery of the State. Some, in that expressive gravity of phiz which becometh senatorial wisdom, will bend their mighty minds to the task of telling the rest of the world how they must behave, and what they must pay; whilst others, treating life and all that appertaineth thereto as a capital joke, will fill their several offices in the State vessel with an air of jollity worthy any jack-tar in the service. The usual amount of personalities, complimentary and the converse, will have to be gone through with proper variations. The aforesaid ship will occasionally be treated to a bit of delicious quietude, or, in plainer phraseology, will be allowed to make no head at all; whilst certain honourable gentlemen are engaged in telling their parliamentary similars what very fine fellows they are, and how desirable it is that the world should be made acquainted with the fact. The flattered gentlemen will then have to look as modest as if merit were no part of their constitution; and, whilst doubting their own claims to the praises lavished on them, swear there is no doubt at all about these said acceptables being abundantly due to their honourable friends on the right and the left.

Then, by way of variety, sundry little tempests will be kicked up by sundry little nobody M.P.'s, who think the best way of becoming popular is to affect to be pugnacious. "Armed to the teeth" with that sort of ferocity which represents anything but courage, and ticklish on certain points of honour which are connected with anything but virtue, one of these verbal belligerents fancies somebody opposite has said or done something personally offensive, and hurls the insinuation at him in a tone to which an ordinary tempest is a zephyr; whilst the suspected party, with a you're another sort of a scowl in his face, makes a reply in the most martial and unmitigated style imaginable. Snarls and snaps then become the "order of the day," until the principals receive the aid of other wordy warriors, who encourage them to proceed, and of certain anti-pistol-and-prizing men, who beg them to desist. They continue the farce, however, until they have fully illustrated that old adage suggestive of "one frightened and the other durstn't," and then they discover that they have both been mistaken, and, after smiling blandly and shaking hands, subside into a calm that is about as much allied to bloodshed as the original threats were to the probability of fulfilment.

Then there are certain other gentlemen who, neither possessed with modesty to keep them quiet, nor with ability enough to make their exertions desirable, are yet determined to do something, though, like Lear, they are not quite sure what it will be. They ask leave to bring in certain bills, the passing of which is about as likely as necessary; but, the courtesies of the "first assembly of gentlemen in Europe" not being denied to even the most insignificant of their number, permission is granted, of course. Then comes the struggle between the senator and the scheme he has got in his head, for raising on his own behalf a blaze of parliamentary triumph. Intense is the anxiety, and killing the effort, for getting the items of this said scheme fairly into letter-press. This at last is done: the parturient throes are over, and the produce is a *mule*. The conception was a false one, and abortion was the result. In the hope of "better luck another time," the father of the piece of failure covers it up and carries it off, with the gratifying promise that on a future occasion he hopes to be able to present them with another specimen of his vigorous paternity.

Now, we do not complain of innocent recreations like these when nobody is concerned in the absurdity but the perpetrators of it. The affair, however, takes a very different complexion in the fact that those who are in front of the scenes have as great a stake in the performance as those who are behind. The good or bad deeds done upon the stage of Parliament are equally felt when ever the influence of that Parliament extends. Men may trifle with their own time, and be prodigal with their own purses, but they have no right to take similar liberties with these said properties of other people. When a set of officials meet together, with the country's approval, for the duties of legislation, they ought to keep an eye upon the necessities of undivided duty. But obligation, and the performance thereof, are sometimes very different things, as the history of the House of Commons not rarely illustrates. Representatives may compliment one another, or quarrel with one another, or even go the almost impossible length of fighting, or may play at framing bills in the absence of the better business of paying them—they may do all these things, and as many other such as they like, but it must be out of school hours. We have an objection to any such Tomfoolery occupying time and attention that ought to be devoted to other objects. Faith, there is enough for ministers and members to do, if they would only do their duty! We throw out these hints for their especial service, preliminary to next session: we hope then to find them as steady and industrious as they ought to be. To prove that they are really so, let them reverse the good old plan of one ministry improving upon another by increasing taxation. Just let them try for once, if it be only for the novelty of the thing, if they cannot take a tax off, instead of putting one on. There is a great bugbear at once to try their strength at—that offensive, inquisitorial Income-tax! Why it was ever imposed, nobody can tell; and why it has been so long submitted to, is as great a mystery. It produces a larger income than the Property-tax of Pitt—rendered necessary by a disastrous war, which we have not seen the semblance of for years. There is no authority whatever for the continuance of an impost like that Income-tax, and we invite the whole press to aid us in putting it down. Upon no man does it fall so heavily and hardly as upon the medical man, in

whose behalf we are determined to use every effort to get the nuisance abolished. Let the organs of other parties, and the press generally, do the same, and the offensive plague will soon be stayed. A succession of shots will bring it to its proper level in the dust, like a dirty thing as it is.

Somewhere in the East, in a certain valley, is a monument, said to have been erected to himself by a king's son, named Absalom, notorious for certain acts of infidelity and undutifulness. At this monument every passer-by casts a stone, in contempt of the individual to whose memory it relates.

The solitary shocks are nothing, but their succession is a cannonading which the structure fails to resist. Slowly, and by piecemeal, it crumbles under the indignity of the several pilgrims who level at it their missiles, and ere long will be hurled the last stone which shall find a mark for scorn to aim at. Let us take a lesson from an Eastern custom, and see if we cannot, with a different weapon, batter down a different nuisance. The Press is the power of this kingdom; let it turn its mighty energies against the evil in question, and the Income-tax will soon cease to exist. For ourselves, it is of little concern how the monster is to be moved: "castigat ridendo mores" is a motto that has "done the state some service," and, in accordance with it, the fun may not be amiss of trying to laugh the evil down. Let every man, or every set of men, when the opportunity serves, whether in high places or low ones, give the impost a regular cachinnatory greeting, indicative at once of its impertinence and absurdity. Let ridicule be thrown upon it by wholesale, and by common consent, and see whether the dirty bargain cannot be shamed out of the hands of the wily authors of it. Moreover, let every man provide himself with anecdotes, names of course omitted, illustrative of the various means by which the imposition is to be evaded. Here is one amongst many that the writer of this article could give. He is physician to an institution which used to pay its resident medical officer one hundred and fifty pounds a year. The man was worth double the sum, and would have had it, but the institution was poor. So was the house-surgeon, for he had a wife, and on the sum aforesaid he could barely manage to live in the manner becoming his station. But the charitable income-tax came to help the poor hard-worked fellow out of his difficulty, by taking the best part of a five-pound-note out of his yearly hard earnings. So the managers took a step in advance of the generous income-tax. They reduced the surgeon's salary to one hundred and forty pounds a year, and gave his wife the odd ten for a Christmas-box. Which was the robbery—the impost or its evasion? Ask the poor fellow's poverty and industry, and you will find a ready answer! How many are there in our profession realizing not more than three guineas a week, and compelled to live at the rate of four, whose delicate family and business secrets are pryed into by impudent officials, as extortionate as any Jew on 'Change! A sad tale, indeed, it would be were every item of overcharge for income against the medical man made public! Many have been the convictions for petty larceny on terms more excusable.

If laughter and ridicule will not avert the abomination, let us try the opposite reasoning. Let it be shown to Government what are a medical man's difficulties in the outset of life—how necessary to success is a concealment of the want

of it—how poor is his remuneration at the best—how much he does for a little recompense, and how much more he does for none: let these things be related, and supported by petition, and presented in due form to the makers and managers of our laws. Such a course could not be without its influence. We know from various communications how severely the tax in question is felt, and by those least capable of bearing it and therefore we urge a speedy and energetic movement for its removal. Let the professor act in concert, and the evil will be overthrown. To that desirable end we will gladly contribute our best efforts.

THE NATIONAL INSTITUTE.

It is a satisfaction to us, considering the advocacy we have given to the National Institute since its formation, to find that it advances in professional favour, and is now firmly established. We nursed, or aided to nurse, it with solicitude during its early days of tentative struggling infancy; and we are now rejoiced to see, from the tenor of the resolutions published in our advertising columns this day, that it feels self-confidence enough to advance its step with the vigour and decision of approved and conscious manhood. It stands alone—it repudiates all extraneous support, save that which it derives from public opinion—the only source of strength to a voluntary body. Doubtless, the old institutions look on with a jaundiced eye, and envy the sturdy vigour and bold carriage of the society they had flattered themselves would be strangled by a convulsion, or would perish as surely, though more gradually, by exhausting inanition. These bodies unquestionably recognise a rival, and, if the Council of the Institute work with zeal and discretion, it will not be long before they also confess a victor.

It will be seen, on perusing the advertisement, that the National Institute reminds the Society of Apothecaries of its duty to its licentiates—a duty which the Society has shown a desire to evade, by throwing the odium of conducting prosecutions against illegal practitioners upon the individual licentiates. We trust that this remonstrance from the Council of the Institute, upon a subject so deeply interesting to every member of the profession, will have its due effect in rousing the Court of Assistants of the Society to a sense of their responsibilities. The members of the profession ought not and, so far as we have the power, shall not be swindled out of their money by false pretences of protection which it is never intended to grant them; and the Society of Apothecaries, or any other corporate body, shall not shuffle out of the performance of its duties by any special pleading or apologetical deprecations which it may choose to offer.

The Society of Apothecaries holds up its hands and, facetiously enough, beseeches forgiveness for its remissness, by a declaration of its poverty, while it is probably receiving four or five thousand pounds a year for the privilege of conferring licenses under the obligation of granting due protection to the holder which, having received the money, it declares itself unable to afford. Where does the money go? Upon whose fingers does it cling? We approve of services being rewarded proportionately to their deserts: but where is the balance-sheet? The profession must inquire into these matters: it must have full information upon them, or they must terminate. The functionaries of the Society may not,

for aught we know, be too liberally rewarded; if this be the case, why do they not justify themselves by publishing an annual balance-sheet? Nothing but publicity can save the character of any society in these days of inquiry and public enlightenment: it is a condition that must be complied with, or suspicion, ill will, and hatred will track every act, and undermine and destroy the fairest fabric that was ever built. Publicity implies responsibility, and responsibility self-government; and this is the springhead of all good government.

Our columns have recently demonstrated the strong feeling that exists among the members of the profession in reference to the inertness of the Apothecaries' Society; and this body may feel assured that, if it allows this feeling to gain strength and to spread very extensively, it will lose all the credit that it has hitherto claimed and received on the ground of its educational discipline, and that, when the time arrives for remodelling the profession, the members will spurn its co-operation, or, at the best, employ it as they would any other unclean thing whose services may be necessary—with disgust.

We have understood that the first meeting of the new Council of the Institute for this year was largely attended, and exhibited much cordiality and confidence in the issue of the cause. There can be no doubt that the bold stand made by the Council against the Registration Bill introduced into Parliament by Thom. Wakley had commanded the respect and reliance of the provincial practitioners, and was mainly instrumental in collecting so large a meeting. We must not forget, also, in estimating the causes of this renewal of interest, the infusion of new blood by the system of election adopted. This periodic introduction of new members cannot fail to maintain an interest in the affairs of the institution, and to give it that vitality, heartiness, and vigour which the decrepit constitutions of the older bodies can neither feel nor receive. It would be useless to put new wine into old bottles: a corpse may be galvanized, but it cannot be reanimated.

The regeneration of the profession is, as we have often told them, in their own hands. Nothing but manliness of assertion and a courageous vindication of right ever yet achieved it, and we are loath to believe that the discrepancies of opinion upon minor points have so far distracted the councils and enfeebled the resolves of the profession that they are incapable of vigorous and honourable action. The profession may rely upon it that another session of Parliament cannot transpire without witnessing another struggle between the advocates of progress, science, and justice, and the jealous bigots and greedy emorants that fasten upon all the honours of the profession and devour all its emoluments. Even these men would feel happier if the struggle were terminated against them, and they were reduced to their proper level in a new organization. The various vibrations and convulsive efforts which they are obliged to make to sustain their equilibrium in the midst of the jostling, the home-thrusts and the by-thrusts which they receive on every side, must make their possession of arbitrary power as burdensome to themselves as it is hateful to the profession.

THE NATIONAL CONVENTION OF POOR-LAW SURGEONS.

We announce with great satisfaction that the proposal of a general Conference of Poor-law

Surgeons has been met with a general and cordial support. In carefully looking through the mass of correspondence with which we have been favoured on this exciting subject, we have encountered but one instance of dissent or opposition. The writer in that case, who is not a poor-law surgeon, bases his protest against a "convention" on such indifferent grounds that they rather add to the force of our appeal than detract from it. The letter is thus worded:—

"SIR,—Ever since the new poor-law has come into operation, the medical public have from time to time been appealed to, by statements of the grievances under which the union doctor groans, in the shape of the arduous duties he has to perform, of inadequate remuneration, and the occasionally offensive conduct on the part of the guardians and the poor-law commissioners. Two letters have lately appeared in your journal from 'A Medical Practitioner,' on the subject of the payment and the duties of a poor-law union doctor (no very respectable title, by the way). Now, Sir, let us inquire how the matter stands between such a person, the public, and the profession, under the present system; and who is to blame—whether the poor-law commissioners, the guardians, or the profession? My opinion is, the only party to blame is the profession. What will be the use of your National Institute? What is the use of your Provincial Associations, or, indeed, any association, if the profession will be traders and cease to be gentlemen? If a man has no respect for himself, does he expect the world will respect him? If he does he will find himself egregiously mistaken. What can justify a man making a greater charge to his private patient than to his public one, bearing in mind the different circumstances of parties? If there is to be any difference, let it be the act of the practitioner, and not be forced upon him. Have not the medical practitioners estimated their own worth? Have they not put their own price upon their services? Have they not degraded themselves? No man who accepts an appointment under any system has cause of complaint; he does so with his eyes open. On the first formation of the unions, did he not contract for his services? Did he try to undersell his neighbour? Did he not tell the world all his former arrangements under the old system were based in cupidity, by accepting the contemptible offers under the new? Then, what right has he to complain, or to call upon his professional brethren to assist him, when at last he finds out he has all along been doing an injustice to himself and them? I think the profession will be most consistent in scouting such complaints for the disgrace the union doctor has brought upon them. Why did he accept the terms he now complains of? He was not forced into it; and if he made an improvident bargain he has himself to blame for it, and has no right to call upon the profession to uphold him: it is by such conduct as this the impudent junta in Lincoln's-inn-fields have dared to insult the profession in the manner they have done; for they believed the general practitioners were all alike (the union doctor a specimen of the whole); and I do hope the respectable part of the profession will not respond to the call of the 'Medical Practitioner,' but let him fight his own battle. I have much more to say upon the subject if the M.P. makes any further appeal.—C."

In much that C. offers us, in relation to the past, we are forced to concur: there is no doubt that there is something to complain of, and more to deplore, in the ready way in which the profession has by one agency or another been made to lend itself to the iniquities of poor-law parsimonies. But the remedy is surely not to leave things as they are. If an amendment be desirable, nay necessary, action is imposed on us as a duty; and we know of no better, no surer machinery for accomplishing a truly beneficial change than the aggregate deliberations, in

one convention, of all the men who have suffered by the grievance, and know both in theory and practice the whole character of its operations and tendencies. If they accomplish the change which lies in their united power, they win a professional amelioration by which, directly or indirectly, all their brethren will be bettered; and no feeling of jealousy or vindictiveness should prevent any of us from holding out to them, in their really interesting struggle, the right hand of sympathy and good fellowship.

Another of our correspondents sends us a suggestion worth a thought:—

"Sir,—Observing from this week's number of your *Times* that your valuable proposition for a Conference of Union Doctors is likely to take effect, I beg to trouble you with one remark, which is, don't you think Birmingham would be a more desirable point than London? The expense would fall heavily on those who reside in the northern parts; for instance, myself: I have only £10 per year for a very extensive district and arduous duties, and I should be very glad to put my shoulder to the wheel and assist to the utmost of my power to extricate myself and my oppressed brother practitioners at such meeting. Hoping you will continue to press the necessity until you obtain the object,

"I am, Sir, yours much obliged,

"A POOR-LAW MEDICAL OFFICER.

"West Derby, Sept. 21."

We are aware that Derby and Birmingham have been more than once recommended for professional meetings on the score of their centrality, but we doubt the justness or superior policy of the suggestion. London is the true centre of England: all men's business and affections converge there. An eighth portion of the English population inhabits that comparatively small area: it is the centre of government, art, science, commerce, and law; and there is scarcely a respectable person in society who cannot profitably as well as agreeably give two days to the sights and friends and business of the great metropolis. It is also most easy of access. Wherefore we hold that London is of all places the best point for a Convention of all English Union Surgeons.

We must solicit forgiveness if, out of the many letters we have received, we can give publicity to comparatively so few. The following is, however, so good itself, and comes from so good a source, that many of our correspondents will be content to have it taken—in connection with those published in other columns—as fair specimens of their intents and wishes. It is from a gentleman who has highly distinguished himself for the zeal and ability he has frequently shown in this cause:—

"Sir,—The poor-law surgeons owe you a debt of gratitude for the part you are taking. I quite agree that a meeting ought to take place as soon as possible, and, if any gentleman will undertake the office of secretary, I undertake to attend, and induce all I can to do the same, and at all events will collect the opinions, &c., of those who live in my neighbourhood. I would suggest that each union should have a meeting, and appoint a delegate to represent its opinions, and to take with him the needful information as to population, acreage, salary, &c.: for I quite agree with your correspondent, Mr. Frankerd, that a fixed rate per head on the population, taking into consideration the acreage and poverty of the different districts, is the only plan that will give satisfaction to the doctors, paupers, and rate-payers.

"I am, Sir, your obedient servant,

"W. CANTRELL, M.R.C.S.,

and POOR-LAW DOCTOR.

"Wirksworth, Sept. 22."

With such cheering indications of general

sympathy and concurrence, there can be as little doubt of the practicability of a *most successful* Convention of Union Surgeons as there has been all along of its expediency. There should be no delay: the sooner some gentleman—why not Mr. Cantrell?—sets himself in communication with every union surgeon the better.

THE NEW SESSION.

THE London machine of Medical Education is again about to be set in motion. The annual work of doctor reproduction is again recommencing. While wishing the affair well, the confession is extorted from us that the progress is more respectable in results than in essence. The schools are too many for their work: the lecturers (several at least) below it: and the students too often have both disqualifications. Yet it is in this way, in the nineteenth century, that we form authorities in whose hands are to be the issues of life and death!

We have heard of many curious parliamentary returns of late: if the inquisitorial principle might be extended, the world would be amused to find the ratio, both in numbers and quality, in which of late years lecturers have stood to students. In numbers our metropolis lecturers would unquestionably have the advantage: how far they would aggregately deserve it in other matters is a point on which, luckily for them, we are not compelled to express an opinion.

Yet, with this droll state of matters, we have in London one medical university and three medical colleges. They are legalized, endowed, and supported to prop up medical education: ask them in what way they accomplish their high destiny, and they respond, "We examine those who pay us!" Ay! They *examine*!

There, however, the system is, and, while burdened by it, lecturers and students have nothing for it but to extract all the utilities it may offer: the one by securing fees and credit; the other by imbibing knowledge and experience. The lecturers know so well how to look after their concerns, that we need offer them no apology for devoting a caution to the students alone.

The young man, when he first takes up his residence in the metropolis, is exposed to many temptations, and he is, perhaps, not in the most advantageous position to resist them, just having escaped from authority, which, probably, had been considered irksome. If, however, time is to be improved, temptations must be resisted; and he who is most diligent at his studies will be the most likely to avoid present temptations, and be the most useful in after life. It is a complaint universally made that, while professional knowledge is making progress, there are yet too many amongst us whose education is defective. The present race of students should endeavour by all means to render themselves especially worthy of an exalted station in the medical commonwealth. Zeal, diligence, self-denial, and courage are requisite here, and he who is not prepared to exercise them had far better now, on the very threshold, give up the idea of entering the ranks of medicine. As we shall in succeeding numbers continue this subject of medical education, we shall now merely add that the student should bear in mind that he is now to store his mind with that knowledge which shall make him *useful* in after life, not with that which will be merely sufficient him to obtain a diploma.

Our friends, the students, will find that in the

very complete guide we have prepared for them, we have omitted the regulations of the University of London. These are of so much interest in connection with reformed medical education, that we have preferred to wait another week in order that we may give them in full, with that commentary on them which their partial excellence, no less than their partial faultiness, calls for.

MR. DERMOTT.

POOR DERMOTT—plain-spoken and persecuted man—has passed from us, to be evermore beyond the reach of the ireful and wicked. Thinking of their sad arts, and sadder acts, one may rejoice at our loss—for with such a life Fortune could have meant him no favour but her *last*. There alone could he hope escape from the troubles of the wicked, and for rest to the weariness of a sad life through!

The career of Mr. Dermott had been cast all through on the shoals and shallows of adversity. Endowed with the qualities of fair talent—great industry, and energy, and temperance—everything the profession had lying apparently open to him—he made no progress in social position, and died as poor a man nearly as on the day he commenced life. The most devoted and one of the most successful cultivators of his science, a mysterious, invisible barrier seemed yet to uprear itself between him and surgical eminence, and an industry of continuous years that would have made him a fortune in any other calling supplied him but at most, and this through years, with his daily bread! In truth a life so useful to others was never so useless to its possessor. The ceaseless activity of a richly-adorned organism was as ill-fated as a very nullity. He has left neither name nor fortune, nor offspring; and, except for his pupils and books, he is as though he had never been!

Mr. Dermott was the son of a medical practitioner of that name, practising for some time in Northamptonshire, but who afterwards left medicine, and entered into holy orders—becoming in the sequel distinguished for his zeal, eloquence, and piety. He is still remembered by his brethren of the Wesleyan Establishment, as a gigantic labourer in the vineyard. His surviving widow arrived in time to see her only child, and one of his oldest friends saw her bending over his emaciated and worn-out frame, ejaculating in the convulsion of grief, "Poor fellow! they have worked him and fretted him to death." Indeed she spoke truly, for never did anatomical teacher work harder—never did one ever so completely fret and gnaw his heart bit by bit—under contumely and injustice!

In following his studies in London, the son became a favourite pupil of Mr. Brookes, and, during this celebrated man's dying illness, supplied his place for six months in the lecture-room. Before his examination at the College of Surgeons, in 1822, the young Dermott derived no inconsiderable pecuniary advantage from his private teachings; and, after that event, he appeared more publicly in connection with a school which he opened in Chapel-street, Wardour-street. The site of the school was changed, first to Great Pulteney-street; then to the Westminster Dispensary, Gerrard-street; and subsequently to Charlotte-street, Bloomsbury, where it remained till 1845, when the Commissioners of Metropolitan Improvements compelled him to dispose of the lease. He then removed to Bedford-square, the scene of his last labours and sufferings.

His health had been failing during the last

three years. He had long been subject to stricture, followed by thickening of the bladder, and had suffered more than one dangerous attack of retention. Latterly, disease of the kidneys made itself felt, and caused him considerable sufferings, which were increased by mental anxieties, caused partly by the conduct of the College of Surgeons, and partly by a curious litigation in which he had become involved through a perverse chain of circumstances. In the year 1843, when the new charter had been given to the College of Surgeons, a medical committee, subsequently known as the Medical Protection Assembly, was formed through the exertions of Mr. Dermott, Dr. Lynch, Mr. Simpson, and a gentleman attached to the staff of this journal. An act of the very basest treachery having transferred the destinies of the "Committee" to the exclusive control of Mr. T. Wakley, Mr. Dermott, resisting tempting overtures and formidable threats, adhered faithfully to the independent principles on which the committee was founded, and to the person through whose aid the body was principally established. Though it was made, in one sense, well worth his while to imitate the conduct of his friends and subscribe to false declarations, support outrageous resolutions, and break closely-bound ties of honour and gratitude, he set his face manfully against the wrong, and among the faithless was found another "Abdiel." He both spoke and wrote against the evil-doing, and at length wholly withdrew himself from the men who were debasing themselves and dishonouring a good cause. His independent conduct, of course, won him bitter hate, and the journal known as "The Lancet" was naturally made, as far as it could be, the instrument of wreaking it. It was while these attacks were going forward that Mr. Dermott gave his students and friends a seasonal *fiat* about the month of April, 1845, in the course of which a student, who had become intoxicated, behaved in an outrageous fashion, and, when remonstrated with, replied by bellowing out accusations against the lecturer of the school, and boasting that he had been sent into the school by Wakley as a spy, and that he would ruin Mr. Dermott. The man was removed from the room, given into custody, and finally was expelled from the school. The self-styled "spy"—it is needless to say—used these circumstances to harass his master by actions for false imprisonment on one side, and for the return of the school fees on the other; and these legal wrongs were, of course, industriously seconded by consecutive attacks from the literary ally—the *Lancet*; and, when it is recorded that a person actually lecturing with Mr. Dermott (a member, we need not say, of our unfortunate profession—Dr. T. Smith) thought there was nothing ungentlemanly or dishonouring in continuing the responsible editor of the very journal that was thus weekly injuring his benefactor and brother-lecturer, it is not difficult to see that Mr. Dermott's malady became as much moral as physical, and that in this and similar circumstances there were agencies at work that gave disease a fatal advantage in a struggle wherein, even with the calmest mind and the best regulated body, nature has often but too much to contend with.

For some time previous to his death, Mr. Dermott was under the able treatment of Mr. Stafford, who, when he found the case assuming a more serious aspect, suggested the attendance of Dr. Prout. An attack of dysentery having supervened, opium was freely administered; vomiting followed, accompanied by extreme feverishness and a marked deterioration of health, which led Dr. Prout to form the worst prognosis. The patient sent for his old friend and fellow-labourer, Dr. Collier, on the Thursday, three days before his death, who had the melancholy task of confirming the opinion already given of his approaching dissolution—a death which Dr. Collier had prognosticated to many, at the period of Mr. Dermott's acute suffering under the public insult and indignity offered to him by that corporate body whose business it ought to

be to nurture and encourage, not to assassinate, talent and industry.

On Sunday, the 12th instant, up to which time he had preserved a self-possession and consciousness rare in such cases, he breathed his last, dying of Bright's disease of the kidney, in his house in Bedford-square, in the 45th year of his age.

Dermott died of renal disease: true: the event is so described in the cemetery record, and posterity will find it so chronicled in the books of the Registrar-General; but he died the martyr of science none the less for that. With a kinder star in the study he worshipped, and happier accessories in the *confères* he lived with, he might and would have lived many a year more with distinction to himself and usefulness to others. He was an honest, worthy, valuable man, and he knew it: he was ill used there, where he had staked his all, and he knew that too: this was the disease that killed him. He bore about him the undying sense of ill usage and contumely: the rulers of his science had set the mark of disparagement on his brow, and in the world there was a ready fool to give credence to the falsehood. Injured and chafing, outraged and fretting, disappointed and wincing, there was a fever of soul kept up within him, through years that wasted away the sap of life and left the frame without resources or refuge when the hour of trial came. Dermott died of natural disease, but he died still the martyr of an abused science.

The surgical council, in excluding Dermott from their body, and in the still grosser act of omitting him from their list of fellows—a miserable use of a most miserable piece of patronage—were the more execrable in their worse than Fulvian cruelty, because of all men breathing he was the man most devoted to anatomy and surgery. He lived and breathed, and thought only in the narrow circle of his science. He was an anatomist and a surgeon—beyond that, nothing. He neither wrote nor spoke of any other subject. In the best sense of the terms he was a "specialist" and a "pure." Astley Cooper—*surgeon*, the only gentleman, and almost the only surgeon, the council has known among its members—rated him as a friend and consulted him as an authority; but the intriguing clique of half-educated and under-bred persons forming the baronet's colleague turned up their noses at the strange honesty and stranger unpretendingness of that *para avis* in "pure" surgery—a man that knew his business—and would not allow, indeed they could not afford to allow him, the collegiate position his scientific claims so much outmerited. Being neither a pretended gentleman nor a pretended surgeon, what claims had he to office? none, certainly none. In place there, he would have been out of place indeed! a good elucidation of the misfortune, in modern chivalric science, of being "pure" in more than name, and "surgeon" in more than official appointment!

As a teacher, our lost friend Dermott was a model of punctuality—regularity—system. For twenty years he scarcely ever omitted a lecture, and when he did he felt it of his honour to make full restitution for the lesson withheld. During the last session he was often seen in the lecture-room when prudence would have commanded his confinement to a bed; and in the coldest days, with disease more than troublesome, daily was he seen doing his vigilant duty in the dissecting-room. The bread he ate he earned—the engagements he made he performed;—how, then, find a friend in T. Wakley, or colleagues in the Council? Under severe wrongs he did a hard duty, which these wrongs made harder. He died beneath the burden.

The style of his lectures was peculiar and characteristic. He was fond of familiar illustration, and not opposed to a humble, if harmless, joke. He imparted knowledge, not elegantly, nor learnedly, but well, and scientifically; brief and interesting enough for the philosopher, and plain and intelligible enough for the simplest and dullest-minded pupil. He knew his subject—said what he knew—and taught what he said.

Nobody could, or ever did, make anatomists quicker or better.

As an author he has done little. He was no discoverer, and he had neither rhetorical cleverness nor inclination to occupy himself in dandling about, in new attitudes, the bantlings of other people. The only works we owe to him are—

1. A Treatise on the Arteries.
2. A Manual on the Bones.
3. An extensive Series of Plates, from Dissections.
4. A clever paper on the Reflections of the Peritoneum.

His practical acquaintance with medical government had not, it is needless to say, increased his reverence for the system; and this subject, therefore, won from him many a contribution through the journals, especially through the *Medical Times*. Writing always publicly—his signature attached—he was not the less bold in his onslaughts; and in a homely, forcible, and, though unslovenly, yet accurate style, the public has received from his fertile pen many denunciations of most of the follies and misdeeds which have increased the need or lessened the chances of that Reform he so ardently desiderated.

His devotion to the cause led to his identifying himself, to some extent, with the *Medical Times* in its infancy, and before it came into the hands of the present management; and to his subsequent attempt at medical journalism, in the shape of the *Medical Record*. If zeal, and earnestness, and energy could suffice to secure success in medical literature, the *Medical Record* might have been still an entity; but Mr. Dermott found after a few months, like others subsequently, that the qualities in which he surpassed his rivals—of whom we were the most friendly—were so few and unimportant, compared with those in which he was matched—that his enterprise might absorb a fortune, without yet establishing a journal. He early, therefore, abandoned the unfortunate project.

The personal appearance of this honest anatomist is so well known to the thousand students whom he fitted for practice, and the many medical men with whom his long surgical career brought him in contact, that we may dismiss it with a very brief recapitulation. In height he was about five feet ten, bulk and shape showing therewith good, though not elegant, proportions. An average-size foot—plainly shod; black trousers, no way remarkable for either "style" or vulgarity; a blue body-coat, closely joined by the intermeditation of bright brass buttons; a hat, worn somewhat jauntily; a fair-sized stick in the hand; a large wolf-looking dog hanging on behind; a cool, negligent, devil-may-care sort of ambulation, such were the outward and visible circumstances of the man that won our observation the first time we encountered him about five years since near Covent-garden. Closer acquaintance showed him to be all these symptoms indicated. He was natural, manly, and independent. He cared for nobody, confided in few, and looked up to none. He formed a rapid judgment on everything, and in most of his convictions there entered as much feeling as reasoning. He felt more strongly than he thought, and, in medical politics, was more for action than investigation. He rarely squared himself by the opinions or feelings of others. He accommodated himself to nobody's hobby, and took off his hat to nobody's prejudices. His doings were after the standard of what was right and expedient in his own mind and heart, and he went about them as if the conflicting predilections and prejudices of an artificial society had neither sway nor existence. He thought them nothing, yet they often stood in his way like brass walls. In short, though practising at times a rude diplomacy, he was thoroughly natural; and, though subject to weaknesses of temper, as of character, thoroughly good.

Phrenologically, or after the teachings of Lavater, there was little offered calling for remark. The head, covered with a half-reclaimed growth of plentiful hair, was full sized, with no

remarkable anterior development; the face, a good-looking aggregation of sufficiently plain features, was in keeping with the configuration of the head; and all, while giving assurance that there was a decided and not commonplace character in the possessor, left spectators without the impression of any extraordinary powers beyond those of energy and good sense.

Dermott was the last of the great anatomical teachers: the school of the Hunters, the Brookes, the Carpuces, and the Dermotts expires in him. He was truly "Ultimus Romanorum."

DEATH OF MR. DERMOTT.

[To the Editor of the Medical Times.]

SIR,—Having read in your Obituary of the death of my friend, George Darby Dermott, recorded as though he had died in the ordinary course of vital deterioration, I think fit to perform a public and private duty, by announcing to the profession that my friend solemnly assured me that he had been assassinated, and that he was suffering a lingering death from the wounds. Should his early friend, the coroner, or the officers of Lincoln's-inn, call an inquest, I shall be glad to give my evidence, and to name the parties. Sir, your humble servant,

G. F. COLLIER.

32, Spring-gardens, Sept. 23.

A CHART OF CHEMICAL ANALYSIS.

The PHARMACEUTICAL TIMES celebrates the first anniversary of its successful establishment by the gift to its subscribers of a very beautiful and complete Chart of Chemical Analysis. The first number of the new volume will be published on Saturday next: a good opportunity for securing, with the two cheapest volumes published in Christendom, a title to this useful present.

The magnificent course of lectures by Müller (illustrated by more than 500 highly-finished engravings), combined with the attention which this journal pays to every department of chemistry and pharmacy, makes it at once interesting and valuable to medical practitioners, and, indeed, to all cultivators of science. The demand for the work, indeed, has been so great as to necessitate the reprint, already, of several numbers. The subscription is the same as to the *Medical Times*, which it resembles in size and form.

Our readers will oblige us by promoting the extension of this journal: they will find that, while well worthy of its cost, it will do honour to their recommendation.

MEETING OF POOR-LAW UNION SURGEONS.

[To the Editor of the Medical Times.]

SIR,—I am delighted to find that you have wielded your powerful pen against the present system of poor-law medical relief; I and many others are very grateful to you for it. Your able leader of last Saturday has aroused me to a due sense of our many grievances; I am, therefore, induced to suggest the following hints for the consideration of my professional brethren, in the hope they may give the matter their most serious attention.

In the first instance, meetings should be held in every union in England and Wales, of the medical officers, and the aid of other medical gentlemen solicited; secretaries appointed for each union; resolutions framed and adopted; memorials drawn up and presented to every board of guardians, containing a temperate statement of our grievances, and of the justice not only of our claims, but of the claims of suffering humanity. Duplicates of such memorials should in every case be forwarded to the poor-law commissioners, and, if it be competent for Parliament to deal with the question, deputations should wait on the members of the House of Commons in their respective districts, enlisting their aid in our cause.

I think, by these simple means, we should stir up a pretty considerable agitation throughout the length and breadth of the land, and would pave the way for a general conference in London, which should be held soon after; and we should never allow the matter to rest until we are completely emancipated.

If only a dozen gentlemen would meet in London, and form a nucleus for a society, and publish an account of their proceedings, I have no doubt they would soon meet with a quick response in the provinces.

I remain, Sir, yours very respectfully,
A PROVINCIAL MEDICAL OFFICER AND
CONSTANT READER.
Sept. 17.

UNION SURGEONS AND THEIR SALARIES.

[To the Editor of the Medical Times.]

SIR,—The list of poor-law medical salaries in your last number has positively made my mouth water. Why, they are magnificent. I served this district for the first five years after the formation of the Spilsby Union for £19, and the population by the last census was 3018. My salary is now £29, having been increased in 1842. I have not thought it worth my while to register all my doings; I have trouble enough without. You will see that my augmented salary is less than half that of some of the districts quoted in your paper.

How long! oh how long! &c. &c.

I am, Sir, your most obedient servant.

R. U. WEST.

Hogsthorpe, Alford, Lincolnshire, Sept. 20.

[To the Editor of the Medical Times.]

SIR,—With yourself, I admire much the straightforward and manly letter of Mr. Frankerd, in your last, on the subject of the remuneration (?) to medical officers of unions.

Nearly four years since, a letter from myself on the same subject appeared in "The Provincial Journal" (Jan. 20, 1844), in which I detailed my grievances, and my notions of the remedy required. But, Sir, to what purpose pour we out our complaints *one to the other*, or publish them in periodicals whose circulation is for the most part confined to the profession? We read, express our sense of the justice of the remarks of "A.B.," or the injustice of the treatment of "C.D."—perhaps give utterance to the wish that something might be done to mend matters—that somebody may come forward to cause their improvement; but ourselves are content to jog on in our daily task, under our own heavy load of grievance, with the apathetic endurance of the countryman, who, never tired of praying to Jupiter, thought not of putting his own shoulder to the wheel. Would it not be far better for us to cease complaining to, and condoling with, each other, and to join heart and soul in endeavouring to procure a remedy for our ailments?

The idea (may I call it *your* idea?) of a Central Convention of Union Doctors, if carried out, would afford us an opportunity for doing something; but let that something be well considered, and our plans well organized, before we act. Let us not quarrel with local boards, or go much into detail of particular grievance, but take our stand upon the broad principle of *fair remuneration for work done*, and that such remuneration be *equalized throughout the kingdom*.

To whom are we to apply for this boon? Not to local boards, certainly. "Keep down the rates" is the cry there; and, however mistakenly, "keep down the salaries" is thought to be a synonymous watchword. The improvements in our situation, hinted at by Mr. Frankerd, have all emanated from the "board above." The vaccination fees, small though they be, were still additions. The fees for fractures and operations, as far as they go, are liberal; and these have again, within the last few weeks, been somewhat extended. These additions have been made by the commissioners; and they also uniformly discourage reduction in salaries, and

I believe that with them the contrary principle is advocated.

From the Commission, then, or from the Government, must come the alteration we wish; and if a memorial signed by the *whole body* of medical officers acting under the new poor-law, respectfully, but firmly, requesting an inquiry into the present state of medical remuneration, were presented by a deputation to the Commission, or to the Home Secretary, such an inquiry would certainly be afforded; and the facts that would appear (for then would be the time for each of us to unfold the causes for dissatisfaction in his own case) must directly make apparent to the Government and the public the necessity of an alteration in the present state of things.

I am, for myself, inclined to think (I submit my opinion in all humility) that, making us altogether Government officers (we are already paid a moiety of our salaries by Government), and having the remuneration regulated according to the number of cases and their distance, and paying us per case, would be equitable and satisfactory. But, whatever the remedy thought most eligible, let it be adopted *unanimously*. "Doctors differ," and never more than when their interests call for unanimity. But this is a question not of relative rank or degree; no disputed point of etiquette, or medical ethics;—to have become union doctors presupposes us qualified practitioners, and as union doctors let us press our just claims. Let us do so temperately, steadily, and perseveringly, and in the proper quarter, and we must eventually overcome all obstacles, the opposition of local boards, and the apathy and indifference of the Government and public generally.

I cannot close this letter without expressing my humble gratitude to the correspondent of the "leading journal of Europe," "S. G. O." A clear-headed and talented man that "S. G. O." The picture drawn in his letter of Sept. 8 is one the original of which has long been known to union doctors, and is a most true and excellent copy from nature. He deserves the thanks of the whole profession for the able manner in which he has brought it before the eyes of the public. To say truth, the medical are not the only subordinates who are hardly worked and miserably paid in the administration of the new poor-law.

Apologizing for the length of this letter, I beg to remain, Sir,

Yours obediently,

HENRY W. LIVETT.

Wells, Somerset, Sept. 22.

WAR-OFFICE, Sept. 17.—22nd Foot: Surg. Samuel Currie, M.D., from 55th Foot, to be Surgeon, vice Campbell, who exchanges.—55th Foot: Surg. Alexander Campbell, from the 22nd Foot, to be Surgeon, vice Currie, who exchanges.

NAVAL APPOINTMENTS.—Surgeon: William Roberts, to the Hecate.—Assistant-Surgeons: Robert P. R. Sparrow, to the Dolphin; James Davidson, to the Kite; T. J. Green, to the Hecate.

APOTHECARIES' HALL.—Gentlemen admitted members on Sept. 16:—George Moseley, Samuel Burgess, and Thomas Parker Rug.

ACCIDENT TO DR. CHINCHALLA.—On the 18th of August Dr. Chinchalla, of Lentia, was wounded in the shoulder by a pistol. The honourable character and well-known moderation of this professor render the outrage inexcusable. Dr. Chinchalla has gained celebrity by the publication of "The Annals of Medicine." We hope that the wound will not prove dangerous.

At a general meeting of the Governors of the Royal General Dispensary, Aldersgate-street, held on Wednesday, the 22nd inst., Dr. Brownless, of Charterhouse-square, physician to the Metropolitan Dispensary, and Dr. Goodfellow, of Bedford-place, Russell-square, were unanimously elected Physicians to the Royal General Dispensary, in the room of Drs. Peacock and Garrod.

THE RULES AND REGULATIONS OF EXAMINING MEDICAL BODIES IN ENGLAND, SCOTLAND, IRELAND, FRANCE, AND GERMANY.

UNIVERSITY OF LONDON.

Examinations for the Degree of Bachelor of Medicine.—Candidates for the degree of Bachelor of Medicine shall be required, 1. To have been engaged during four years in their professional studies at one or more of the institutions or schools recognised by this university. 2. To have spent one year at least of the four in one or more of the recognised institutions or schools in the United Kingdom. 3. To pass two examinations.

The first examination shall take place once a year, and commence on the first Monday in August. No candidate shall be admitted to this examination unless he have produced certificates to the following effect:—1. Of having completed his nineteenth year. 2. Of having taken a degree in arts in this university, or in a university the degrees granted by which are recognised by the senate of this university; or of having passed the matriculation examination. 3. Of having been a student during two years at one or more of the medical institutions or schools recognised by this university, subsequently to having taken a degree in arts, or passed the matriculation examination. 4. Of having attended a course of lectures on each of four of the subjects in the following list:—Descriptive and Surgical Anatomy, General Anatomy and Physiology, Comparative Anatomy, Pathological Anatomy, Chemistry, Botany, Materia Medica and Pharmacy, General Pathology, General Therapeutics, Forensic Medicine, Hygiene, Midwifery and Diseases peculiar to Women and Infants, Surgery, Medicine. 5. Of having dissected during nine months. 6. Of having attended a course of Practical Chemistry, comprehending practical exercises in conducting the more important processes of general and pharmaceutical chemistry; in applying tests for discovering the adulteration of articles of the materia medica, and the presence and nature of poisons; and in the examination of mineral waters, animal secretions, urinary deposits, calculi, &c. 7. Of having attended to practical pharmacy during a sufficient length of time to enable him to acquire a practical knowledge in the preparation of medicines.

These certificates must be transmitted to the registrar at least fourteen days before the commencement of the examination. The fee for this examination is five pounds. No candidate can be admitted to the examination unless he have previously paid this fee to the registrar; and if he fail to pass the examination, the fee will be returned to him.

The candidates are examined in the following subjects:—Anatomy, Physiology, Chemistry, Structural and Physiological Botany, Materia Medica, and Pharmacy.

The examinations are conducted in the following order:—Morning, 10 to 1; Monday, Anatomy and Physiology, by printed papers;

Tuesday, Chemistry, by experiment and printed papers. Afternoon, 3 to 6; Monday, Anatomy and Physiology, by printed papers; Tuesday, Botany, Materia Medica, and Pharmacy, by printed papers. To commence on Friday at 10. Chemistry, Materia Medica, and Pharmacy, by *viva voce*, and demonstration from specimens. To commence on Monday, in the following week, at 10: Anatomy and Physiology, by *viva voce*, demonstration from preparations, and dissection.

On the Wednesday morning in the week following the commencement of the examination, the examiners will arrange, in two divisions, each in alphabetical order, such of the candidates as have passed: and a pass certificate, signed by the registrar, will be delivered to each candidate. Such candidates only as in the opinion of the examiners are admissible to the examination for honours, shall be placed in the first division.

Examination for Honours.—Any candidate who has been placed in the first division at the first examination, may be examined for honours in any or all of the following subjects:—Anatomy and Physiology (candidates may illustrate their answers by sketching the parts they describe), Chemistry, Materia Medica, and Pharmaceutical Chemistry.

These examinations take place in the week following the commencement of the first examination. They are conducted by means of printed papers; but the examiners are not precluded from putting *viva voce* questions upon the written answers of the candidates when they appear to require explanation. The examinations for honours are conducted in the following order:—Morning, 10 to 1: Thursday, Anatomy and Physiology; Friday, Chemistry. Afternoon, 3 to 6: Thursday, Anatomy and Physiology; Friday, Materia Medica and Pharmaceutical Chemistry.

If in the opinion of the examiners sufficient merit be evinced, the candidate who shall distinguish himself the most in Anatomy and Physiology, the candidate who shall distinguish himself the most in Chemistry, and the candidate who shall distinguish himself the most in Materia Medica and Pharmaceutical Chemistry, shall each receive an exhibition of thirty pounds per annum for the next two years. Under the same circumstances, the first and second candidates in each subject shall each receive a gold medal of the value of five pounds.

Second Examination.—The second examination takes place once a year, and commences on the first Monday in November. No candidate can be admitted to this examination within two academical years of the time of his passing the first examination, nor unless he have produced certificates to the following effect:—1. Of having passed the first examination. 2. Of having, subsequently to having passed the first examination, attended a course of lectures on each of two of the subjects comprehended in the foregoing list, and for which the candidate had not presented certificates at the first examination. 3. Of

having, subsequently to having passed the first examination, dissected during six months. 4. Of having conducted at least six labours. (Certificates on this subject will be received from any legally-qualified practitioner in medicine.) 5. Of having attended the surgical practice of a recognised hospital or hospitals during twelve months, and lectures on clinical surgery. 6. Of having attended the medical practice of a recognised hospital or hospitals during other twelve months, and lectures on clinical medicine. 7. Of having, subsequently to the completion of his attendance on surgical and medical hospital practice, attended to practical medicine in a recognised hospital, infirmary, or dispensary, during six months. (Certificates on this subject will be received from any legally-qualified practitioner having the care of the poor of a parish.) The candidate must also produce a certificate of moral character from a teacher in the last school or institution at which he has studied, as far as the teacher's opportunity of knowledge has extended. The certificates must be transmitted to the registrar at least fourteen days before the examination begins. The fee for this examination is five pounds.

Candidates are examined in the following subjects:—Physiology (the papers in Physiology including questions in Comparative Anatomy), General Pathology, General Therapeutics, Hygiene, Surgery, Medicine, Midwifery, Forensic Medicine. The examination is conducted in the following order:—First Week. By printed papers. Morning, 10 to 1: Monday, Physiology; Tuesday, Surgery; Wednesday, Midwifery. Afternoon, 3 to 6: Monday, General Pathology, General Therapeutics, and Hygiene; Tuesday, Medicine; Wednesday, Forensic Medicine.—Second Week. By *viva voce* interrogation. To commence on Monday morning at 10.

On the Monday morning in the following week, the examiners will arrange, in two divisions, each in alphabetical order, such of the candidates as have passed; and a certificate under the seal of the university, and signed by the chancellor, will be delivered to each candidate. Such candidates only as in the opinion of the examiners are admissible to the examination for honours will be placed in the first division.

Examination for Honours.—Any candidate who has been placed in the first division at the second examination, and has produced a certificate showing that he has not completed his twenty-fifth year, may be examined for honours in any or all of the following subjects:—Physiology and Comparative Anatomy (candidates may illustrate their answers by sketching the parts they describe); Surgery, Medicine, Midwifery, Structural and Physiological Botany.

The examination for honours will take place in the week following the second examination. It will be conducted by means of printed papers; but the examiners are not precluded from putting *viva voce* questions upon the written answers of the candidates when they appear to require explanation. The examination is conducted in the following order:—Morning, 10 to 1: Tuesday,

Physiology and Comparative Anatomy; Wednesday, Surgery; Thursday, Medicine; Friday, Midwifery. Afternoon, 3 to 6: Tuesday, Physiology and Comparative Anatomy; Wednesday, Surgery; Thursday, Medicine; Friday, Structural and Physiological Botany.

If in the opinion of the examiners sufficient merit be evinced, the candidate who shall distinguish himself the most in Physiology and Comparative Anatomy, the candidate who shall distinguish himself the most in Surgery, and the candidate who shall distinguish himself the most in Medicine, shall each receive an exhibition of fifty pounds per annum for the next two years, with the style of University Medical Scholar. Under the same circumstances, the first and second candidate in each of the preceding subjects shall each receive a gold medal of the value of five pounds. Under the same circumstances, the candidate who shall distinguish himself the most in Midwifery, and the candidate who shall distinguish himself the most in Structural and Physiological Botany, shall each receive a gold medal of the value of five pounds.

Examination for the Degree of Doctor of Medicine.—The examination for the degree of Doctor of Medicine takes place once a year, and commences on the fourth Monday in November. No candidate can be admitted to this examination unless he have produced certificates to the following effect:—1. Of having taken the degree of Bachelor of Medicine in this university, or a degree in medicine or in surgery at a university, the degrees granted by which are recognised by the senate of this university. Those candidates who have not taken the degree in this university shall produce a certificate of having completed their twenty-third year. 2. Of having attended, subsequently to having taken one of the above degrees in medicine, (a) to clinical or practical medicine during two years in a hospital or medical institution recognised by this university; (b) or, to clinical or practical medicine during one year in a hospital or medical institution recognised by this university, and of having been engaged during three years in the practice of his profession; (c) or, if he have taken the degree of Bachelor of Medicine in this university, of having been engaged during five years in the practice of his profession. (One year of attendance on clinical or practical medicine, or two years of practice, will be dispensed with in the case of those candidates who, at the second examination, have been placed in the first division.) 3. A moral character, signed by two persons of respectability.

These certificates must be transmitted to the registrar at least fourteen days before the examination begins. The fee for the degree of Bachelor of Medicine is ten pounds.

Candidates are examined in the following subjects:—Elements of Intellectual Philosophy, Logic, and Moral Philosophy; Medicine. The examinations are conducted in the following order:—By printed papers, Morning, 10 to 1. Monday, Elements of Intellectual Philosophy, Logic, and Moral Philosophy. (Candidates who have taken a degree in arts in this university, or in a university the degrees granted by which are recognised by the senate of this university, are exempted from this part of the examination. The degrees in arts of all universities in the United Kingdom are recognised by the senate for this purpose.) Tuesday, Medicine. Afternoon, 3 to 6. Monday, a Commentary on a case in Medicine, Surgery, or Midwifery, at the option of the candidate. Tuesday, Medicine, by *viva voce* interrogation. Friday morning, at 10, examination on the answers to the Printed Papers, and on the Commentaries; and the examination for a certificate of Special Proficiency in Medicine, Surgery, or Midwifery, as determined by the candidate's choice of the case for commentary.

On the Monday morning in the following week the examiners will arrange in two divisions, each in alphabetical order, such of the candidates as have passed; and a certificate under the seal of the university, and signed by the chancellor, will be delivered to each candidate. Such candidates

only as, in the opinion of the examiners, are admissible to the examination for honours, will be placed in the first division. If, in the opinion of the examiners, sufficient merit be evinced, the author of the best Commentary on the Case in Medicine, the author of the best Commentary on the Case in Surgery, and the author of the best Commentary on the Case in Midwifery, will each receive a gold medal of the value of five pounds. Any candidate may present a thesis on a subject of his own choice. If, in the opinion of the examiners, sufficient merit be evinced, a gold medal of the value of ten pounds, will be given to the author of the best thesis. The examiners are not precluded from examining the author on the subject of his thesis.

Examination for Honours.—Any candidate who has been placed in the first division may be examined for honours in any or all of the following subjects:—Surgery, Medicine, Midwifery. The examinations take place in the week following. They are conducted by means of printed papers; but the examiners are not precluded from putting *viva voce* questions upon the written answers of the candidates when they appear to require explanation.

The examinations for honours are conducted in the following order:—Morning, 10 to 1: Tuesday, Surgery; Wednesday, Medicine; Thursday, Midwifery. Afternoon, 3 to 6: Tuesday, Surgery; Wednesday, Medicine; Thursday, Midwifery.

If, in the opinion of the examiners, sufficient merit be evinced, the first candidate in each subject will each receive a gold medal of the value of five pounds.

Institutions and Schools.—No medical institution or school is recognised by the senate of this university which does not possess ample means of illustrating the instruction given at it. **Forms of Certificates.**—The teacher must certify for—**Lectures.**—That in the year 18 . . . , the pupil attended . . . his course of instruction on . . . and terminated at . . . and which consisted of . . . lectures and . . . examinations. **Practical Anatomy.**—That from . . . to . . . the pupil dissected . . . under his superintendence. **Practical Chemistry.**—That the pupil operated . . . during his course of Practical Chemistry, which consisted of . . . lessons. **Practical Pharmacy.**—That the pupil prepared . . . medicines under his superintendence from . . . to . . .

Clinical Instruction in Surgery.—That the pupil attended . . . the surgical practice of this hospital, and the course of lectures on Clinical Surgery, consisting of . . . lectures, from . . . to . . . **Clinical Instruction in Medicine.**—That the pupil attended . . . the medical practice of this hospital, and the course of lectures on Clinical Medicine, consisting of . . . lectures from . . . to . . .

Practical Medicine.—That the pupil attended . . . to Practical Medicine at . . . and was intrusted with the treatment of patients under . . . superintendence, from . . . to . . . (Certificates on this subject will be received from any legally-qualified practitioner, having the care of the poor of a parish.) **Practical Midwifery.**—That the pupil conducted . . . labours under his superintendence. Any legally-qualified practitioner shall be competent to give this certificate.

Regulations relating to Students who commenced their Medical Studies in or before January, 1840. **Degree of Bachelor of Medicine.**—Candidates who commenced their professional studies in or before January, 1840, are admitted to the first examination for the degree of Bachelor of Medicine on producing certificates to the following effect:—1. Of having been engaged during two years in their professional studies. 2. Of having attended a course of lectures on each of four of the subjects comprehended in the former list. 3. Of having dissected during nine months. 4. Of having attended to practical pharmacy during a sufficient length of time to enable them to

acquire a practical knowledge in the preparation of medicines.

Candidates who commenced their professional studies in or before January, 1840, are admitted to the second examination for the degree of Bachelor of Medicine on producing certificates to the following effect:—1. Of having been engaged during four years in their professional studies. 2. Of having passed the First Examination. 3. Of having attended a course of lectures on each of two of the subjects comprehended in the former list. 4. Of having dissected during twelve months. 5. Of having attended to practical pharmacy during a sufficient length of time to enable the pupil to acquire a practical knowledge in the preparation of medicines. 6. Of having conducted at least six labours. 7. Of having attended the surgical practice of a recognised hospital or hospitals during twelve months. 8. Of having attended the medical practice of a recognised hospital or hospitals during other twelve months. 9. Of having completed the twenty-second year of their age. 10. Of moral character, from a teacher in the last school or institution at which they have studied, as far as the teacher's opportunity of knowledge has extended.

Candidates who have not taken a degree in Arts, or passed the Matriculation Examination in this university, will be required to translate a portion of *CELSUS de Re Medica*.

Regulations relating to the Practitioners in Medicine or Surgery desirous of obtaining Degrees in Medicine.

Degree of Bachelor of Medicine.—Candidates are admitted to the two examinations for the degree of Bachelor of Medicine on producing certificates to the following effect:—1. Of having been admitted, prior to the year 1840, members of one of the legally-constituted bodies in the United Kingdom for licensing practitioners in medicine or surgery, or of having served, previously to 1840, as surgeons, or assistant-surgeons, in her Majesty's Army, Ordnance, or Navy, or in the service of the Honourable the East India Company. 2. Of having received a part of their education at a recognised institution or school, as required by the charter of the university. 3. Of moral character, signed by two persons of respectability.

Candidates who have not taken a degree in Arts, or passed the Matriculation Examination in this university, will be required to translate a portion of *CELSUS de Re Medica*.

Degree of Doctor of Medicine.—Candidates who have been engaged during five years in the practice of their profession, may be admitted to the examination for this degree on producing certificates to the following effect:—1. Of having been engaged during five years in the practice of their profession. 2. Of having taken the degree of Bachelor of Medicine in this university.

Candidates who have not taken a degree in Arts, or passed the Matriculation Examination in this university, will be required to translate a portion of *CELSUS de Re Medica*.

The regulations respecting the transmission of the certificates to the registrar, the fees, the periods, and the mode of conducting the examinations, and the arrangement of the candidates after examination, are the same for all candidates for the same degrees.

A NEW COLLEGE AT ATHENS.—A Medical Academy has just been established at Athens. Dr. Dumanos Georgios is perpetual secretary.

SCIENCE IN EGYPT.—The Egyptian Government wishes to give every possible guarantee to Europe for the quarantine service. It will double the number of Arabian and European doctors throughout Egypt. The number of pupils in the Medical School at Cairo is to be increased, also, in the same proportion.

LUNATIC ASYLUMS IN RUSSIA.—For a long time there has been but one district establishment in Russia for insane persons: it is situated at St. Petersburg. The Government intends to establish others in the city of Moscow, Kazan, Charkow, Keiv, Odessa, Wilna, and Riga.

SUGGESTIONS

FOR A MORE SIMPLE ARRANGEMENT OF THE

MATERIA MEDICA,

BASED ON ITS PHARMACEUTICAL AND THERAPEUTICAL RELATIONS.

By GEORGE LEITH ROUPELL, M.D.

Cantab., F.R.S., Fellow of the Royal College of Physicians, Physician to St. Bartholomew's Hospital, Lecturer on Materia Medica at the College of St. Bartholomew's Hospital.

(Continued from p. 584.)

LECTURE X.

The next order of which I have to treat is the VII. Drugs which owe their Efficacy to Gum and its Alliances.

Gum is well known as a mucilaginous juice exuding naturally from, or obtained by making artificial incisions in, certain trees, those chiefly of tropical climates. This juice concretes by exposure to the air, and by the heat of the sun, into hard, transparent, irregular masses. Its great characteristic is the formation of mucic acid when it is acted upon by dilute nitric acid, mucic acid appearing as a white crystalline powder, crackling in the teeth. Gum contains two principles, arabine and bassorine—the one soluble in water, the other not. Gum arabic is to be taken as the type of the purest specimen of this order. This is soluble in its own weight of water, is insoluble in alcohol, and occasions a dense curdy precipitate with diacetate of lead; a precipitate by the neutral acetate of lead distinguishes the mucilages which are allied to the principle now under consideration. It deserves notice that, by heat and the action of acids, a substance resembling gum may be made from starch: to this the term dextrine has been given.

Gum forms a smooth, lubricating, mucilaginous solution which is beneficial in various cases of irritation of the mucous membranes of the chest, bowels, or kidneys. It is used to form pill masses, but is apt to render them hard. By its means powders, fixed and volatile oils, and resins may be suspended in water.

The following are the plants referred to in the Pharmacopœia as the chief sources of gum and its alliances:—

43. Gum or mucilage from—
Acacia vera.
Astragalus verus.
Cydonia vulgaris.
Althœa officinalis.
Malva communis.
Linum usitatissimum.

The next order is composed of

VIII. Drugs Chiefly Introduced on Account of the Starch which they Contain.

Of the importance of this principle all, I presume, are aware. Its chemical relations are highly interesting; its conversion, for example, into dextrine and sugar on the one hand, and into fixed oil and fat on the other, are striking instances of the metamorphoses of principles. It constitutes one great source of the nutrition both of plants and animals, abounding in the seeds of the cereals, the stems of the pulms, and the roots of many of the vegetable orders.

Starch may readily be detected by its own peculiar features. It exists in the form of small rounded brilliant grains, varying in size from $\frac{1}{100}$ to the $\frac{1}{1000}$ of an inch in diameter. These grains are described by M. Raspail as vesicles filled with a hardened mucilaginous or gummy matter, bursting in water at a temperature about 140° F., and remaining in suspension in the fluid while the enclosed matter dissolves in it. Others describe these grains as composed of layers, the outer one of which is the thickest, and may be dissolved by continued ebullition or broken by grinding it with any hard powder. These grains or vesicles vary in shape as well as size; those procured from wheat-flour are the smallest, those from the potato are the largest; some are globular, some ovoid, others again are

angular, peculiarities by which they may easily be distinguished by a practised eye, aided by the microscope. The formula of starch, dried at an ordinary temperature, is $C^{12}H^{10}O_5 + 2aq$. When pressed in the fingers it gives a peculiar sound, and it is coloured blue on the addition of iodine; when boiled, however, with diluted acids, it is first coloured purple by iodine, this afterwards ceases to have any effect upon it, and then it will be found to have been converted into dextrine. The presence of starch in the pollen of plants; its deposition in the stem of perennial shrubs and trees; its conversion in the spring into gum and sugar by the action of "diastase," which is naturally generated during germination; and the probable conversion of starch by its decovadation into the fixed oils and fats, are not only interesting as physiological facts, but are valuable as showing the simple means by which such different results may be obtained, and give connection to some of the various heads under which I have endeavoured to class what was anciently termed the "simples" of the materia medica. I shall not dwell further on the varieties of starch, but shall briefly mention its uses in medicine, and then enumerate the plants from which we chiefly procure it.

Starch is chiefly employed in medicine as an emollient, as a lubricating injection, and occasionally as a soothing drink. It is the vehicle for opium in the *emœna opii*, and it is serviceable in the form of powder as a means of defending abraded surfaces from friction. Compresses steeped in a solution of starch become hard when dry, and afford an excellent support in certain cases of fractured limbs.

Dietetically, starch is largely used as a mild non-stimulating aliment; and, according to the most modern view, it is looked upon as one of the great sources of animal heat through the agency of the respiratory process. Suffice it to say that starch is essentially a vegetable product undergoing complete transformation by the agency of the digestive process. We chiefly procure—

44. Starch from—
Triticum hybernum.
Hordeum distichon.
Avena sativa.
Secale cereale.
Oryza sativa.
Zea mays.
Sagittaria arifolia.
Maranta arundinacea.
Solanum tuberosum.
Inula helenium.

IX. Drugs used on Account of their Saccharine Matter.

Sugar abounds in the nectaries of most flowers; in the roots of many plants, as in the potato, the carrot, the beet, &c.; in the juice of very many, though abounding particularly in some, as the cane, the palm, and maple. Sugar is found in milk, and is the product of mal-assimilation in one interesting disorder, diabetes.

The conversion of starch into sugar has already been alluded to—a change which takes place in the maturation of fruits, and in the germination of plants. Other substances, too, less tractable apparently in their nature, can be made to undergo this alteration—woody fibre, for example, and even the bitter neutral principle, salicine. Gelatine also, by the action of sulphuric acid, yields fermentable sugar.

There are two varieties which require notice, the cane, namely, and the grape-sugar. The formula of the cane-sugar is $C^{12}H^{22}O^{11} + 2aq$. This is the variety found in flowers, in beetroots, and is the one commonly employed to impart a sweet taste.

Grape-sugar has for its formula $C^{12}H^{24}O^{14}$. This it is which gives the sweet taste to grapes: it is the product of the action of acids on woody fibre, on starch, and on sugar of milk. It is the form met with in diabetes. Honey contains it in a particular state, and cane sugar itself is converted into this form when treated with diluted acids.

Grape-sugar is less soluble, and dissolves more slowly in water than cane-sugar, and two and a half parts of grape-sugar are required to produce in a liquid the same degree of sweetness as one of cane.

Chemical analysis detects sugar very extensively, indeed, in vegetable juices even where it would be *a priori* little suspected, as, for example, in the bitter root of the gentian.

Some kinds are fermentable, others not; and we are familiar with sugar in the crystalline form, or in that of an amorphous transparent mass. Sugar is extensively used in pharmacy, medicine, and as an aliment. It is used, for example, in pharmacy to preserve many substances, both vegetable and mineral, from decomposition, when it appears under the title of a syrup, an electuary, a conserve, a confection, or a saccharate. It is largely employed in making lozenges. It is sometimes mixed with scammony, jalap, and other aperient powders, from a supposed power of mitigating their activity; and it enables us to suspend more largely camphor and the volatile oils in water. In medicine sugar, variously combined, is constantly employed in cases of irritation about the larynx and trachea. Applied to parts denuded of their cuticle, or to the surface of ulcers, it stimulates the vessels, and thus aids in the process of reparation. It would appear even to irritate the sound membrane of internal parts, as it was in solution the ordinary laxative enema in the time of Sydenham. It has been recommended in cases of poisoning by copper, bichloride of mercury, and the salts of lead, as an antidote; but the question of its efficacy is not determined, and we have in albumen and the soluble sulphates more certain remedies.

A few words must be said about sugar as an alimentary substance. Naturally intended as a provocative to the appetite, and as naturally combined an admirable adjunct to other nutritive principles, taken in excess in its pure form, it is highly injurious, and in some disorders is itself little short of a poison. In diabetes and in the oxalic acid diathesis it is most pernicious; and in all constitutions, if largely indulged in, it is liable to occasion dyspepsia, emaciation, softening of the gums, and excess of lithic acid.

I have now to refer to the chief sources of this principle, which, in various states of combination, is yielded by the following plants:—

45. The saccharine principle as obtained from—

- Saccharum officinarum.*
Ficus carica.
Pinus domestica.
Cassia fistula.
Rosa canina.
Vitis vinifera.
Mel.

Fraxinus ornus.
Glycyrrhiza glabra.

Under the head "Saccharine Principle" I propose to consider the conversion of it into alcohol and into acetic acid, selecting that especial source from which these products are usually obtained commercially, or were originally procured. Under the head, therefore, of the "Vino" I shall treat of alcohol and ether, as also of vinegar. The leading facts of these interesting transformations will be briefly detailed, and the pharmaceutical uses, with the good and ill effects of these products upon the system, will then be considered. Few subjects have of late years attracted more attention than the injury to the health occasioned by the habitual use of alcoholic drinks, and the philanthropist has shown incontestably to the intemperate the rashness and folly of his course. Still, out of these very so-called evils has sprung one of the greatest blessings yet conferred by any one person on his race—the means, namely, suggested by Dr. Morton, of Boston, of obviating the pain of operations by the sedative effect of the vapour of ether.

I shall conclude in my next this arrangement of the organic principles by the consideration of the organic acids, the various colouring matters, and albumen.

ON THE PHYSICAL PHENOMENA OF LIVING BODIES.

By Professor MATTEUCCI, of Pisa.

PART XV.

CIRCULATION OF THE BLOOD.

(Continued from p. 586.)

We have now to speak of the pressure which the blood supports in the vessels. The investigation of this point has occupied the attention of physiologists in all ages; but widely different roads have been followed by them in their respective researches. The same may be said of the investigations regarding the force with which the left ventricle of the heart contracts.

Borelli, Bernoulli, and Keil arrived at vastly different results in this respect. Thus, whilst Borelli estimates the force of the heart as equivalent to a force capable of sustaining 100,000 pounds, Keil estimates it as low as five ounces.

Hales was the first to make accurate experiments for the purpose of measuring the pressure of the blood in the arteries; but it is to Poiseuille that we are indebted for the most complete researches into this important subject.

Poiseuille's hemo-dynamometer consists of a species of glass manometer, the short and horizontal branch of which is inserted into a brass tube, which latter is subsequently introduced into one of the arteries of a living animal. To prevent the coagulation of the blood, which, were it permitted to occur, would obstruct the portion of the tube situated between the artery and the column of mercury, Poiseuille recommends to fill this portion first with a solution of carbonate of soda. When the tube is inserted into the artery, the mercurial column is seen to rise to a certain height, at which it remains subsequently stationary during the whole of the time that the experiment is made to last. The difference of level between the two columns of mercury indicates likewise the degree of pressure exerted by the blood against the corresponding section of the wall of the vessel into which the tube of the apparatus has been introduced. Poiseuille made a great many experiments with this instrument upon the arteries of divers animals, and also upon different arteries of one and the same animal. The most important fact deduced from the results of these experiments is this—the pressure of the blood in the arteries is uniform, the same, whatever the point of the arterial system, the diameter of the vessel, its distance from the heart, and the position of the ramification experimented upon, relatively to the trunk from which it springs. Thus Poiseuille found that the instrument indicated the same pressure when applied upon the carotid of a dog at a distance of 180 millimetres from the heart as when

applied upon the aorta at a distance of 370 millimetres from the heart: the diameter of the aorta experimented upon being nine millimetres, that of the carotid four millimetres. In both cases the pressure was measured by a column of mercury of 84 millimetres. The same result was obtained in experiments upon two different arteries of a horse: the diameter of one of those arteries was five times that of the other. The pressure exerted by the blood in both was equally measured by a column of mercury of 146 millimetres. It is curious that the pressure which the blood exerts to support respectively in the several animals bears no relation whatsoever to the respective weight of the animals.

The uniformity of the pressure exerted by the blood in the several vessels of the animal body, which has thus been demonstrated by Poiseuille, is the necessary consequence of the principle of equality of pressure: the shock given by the column of blood expelled from the left ventricle against that which is contained in the aorta is instantly propagated equally throughout the whole mass of the blood in the large and small arteries.

It is this shock, which is repeated each time the ventricle propels blood into an artery and its ramifications, that produces the well-known phenomenon of the pulse, which we know to be isochronous with the contraction of the ventricle.

The numbers supplied by Poiseuille's experiments indicate, accordingly, the amount of pressure supported by the walls of the heart and arteries: this pressure is constantly equivalent to the weight of a column of mercury having for base the area of the artery, or the superficies of the ventricle, and for height the elevation marked by the hemo-dynamometer. From these data Poiseuille was enabled to calculate that at the moment of the contraction of the heart of a young man aged twenty-nine, (a) the blood rushes into the aorta, exerting against the liquid column which fills the latter (assuming this column to be in a state of rest) a pressure measured by 1.971779 kilogramme. In the radial artery this pressure would be reduced to 15.35 grammes. Could we know accurately the extent of the internal surface of the left ventricle at the moment of contraction, we might readily estimate the amount of pressure exerted at that moment upon the walls of the ventricle.

The constancy of the variations observed in the elevation of the mercurial column in the hemo-dynamometer, during the respiratory movements, is one of the most important results of Poiseuille's experiments: this elevation is constantly more considerable during expiration than during inspiration; this difference is observed equally in the large and the small vessels; but it is more or less considerable, according to the several classes of animals.

The elevation of the mercurial column in the hemo-dynamometer varies also with the respective position in which the animal happens to be placed. The author observed invariably that, the instrument being introduced into the carotid, the mercurial column rose several millimetres whenever the animal was lifted up by its hind part, and fell, on the contrary, whenever the opposite manœuvre was practised upon it. The cause of this difference is evident; and we must accordingly assume that Poiseuille, in his comparative experiments upon the pressure respectively exerted by the blood in the different vessels, kept the animal experimented upon constantly in one and the same position.

The dilatation of the arterial tubes which occurs at the arrival of each successive wave of blood is a fact deserving a few brief remarks. It is, again, to Poiseuille that we are indebted for the experiment proving, beyond doubt, the existence of this phenomenon, which exercises so great an influence upon the circulation of the

blood. The experiment alluded to is conducted as follows:—A certain space of the course of the carotid artery of a live horse is laid bare and enclosed in a metallic tube filled with water; this tube has an aperture which is then closed with a perforated cork, to which a glass tube of small diameter is fitted. At every contraction of the left ventricle, the liquid column rises in the tube, and recedes again when the contraction ceases; thus the dilatation of the artery occasioned by the impulsion of the column of blood is succeeded by the re-contraction of the arterial walls to their usual size by virtue of their elasticity. Poiseuille has endeavoured to measure this force of elasticity displayed by the arterial walls; we will not go quite so far as to admit the correctness of his results, viz., that the force with which the walls of the artery contract exceeds the force which dilated them; but this much is certain, that an additional propelling force is supplied by the contraction of the arterial walls succeeding the contraction of the ventricle.

Poiseuille has also studied the question of the movement of the blood in the capillaries. He saw the movement of the blood in the capillaries cease upon removing or tying the heart; the movement certainly persisted for a few moments, but this is ascribable simply to the diminution of volume and a species of contraction which the elastic walls of the vessel experience when the blood ceases to be propelled by the heart. With the aid of the microscope, a layer of serum, perfectly stationary and motionless, is seen adherent to the walls of the vessel, and the sanguineous liquid is thus seen moving in a tube formed by its own substance. Poiseuille has studied the flow of liquids, both in capillary tubes of glass and in capillary vessels, of live and of dead animals; he found the same laws presiding over it in the capillaries as in the glass tubes. This fact demonstrates clearly that in these different cases the liquid circulates actually in a tube formed invariably of one and the same material, viz., a stationary liquid stratum of its own substance adherent to the walls of the tube, no matter what the nature of the material of the latter. It is a curious fact that the capillary circulation is not influenced by variations of the atmospheric pressure; it continues the same *in vacuo* as under a pressure of from eight to ten atmospheres.

After this detailed exposition of the most precise and conclusive experiments on the divers questions relating to the circulation of the blood, we will now proceed to elucidate the mechanism of circulation from the data supplied by the results of these experiments.

It would be superfluous to adduce any further proof of the fact that the contraction of the heart, and the elasticity of the vascular and, more particularly, of the arterial walls, are the principal motive powers in the sanguineous circulation.

We will confine ourselves here to cite an experiment of Magendie's:—The crural artery and crural vein of a dog are laid bare, and a ligature is passed round the vein: upon making an incision in the vein below the ligature, a jet of blood escapes from the aperture; upon compressing the artery the jet of blood from the vein diminishes, and ceases finally altogether, except the compression be removed from the artery, when the jet will at once reappear: these alternations may be reproduced several times. The deduction to be drawn from this fact is evident: the blood traverses the capillaries and circulates through the veins by the sole action of the forces which propel it in the arteries, viz., the contraction of the left ventricle, and that of the arterial walls.

The atmospheric pressure can exercise only a very limited influence upon the circulatory function. We have already remarked that the mercurial column of a hemo-dynamometer, applied to an artery, rises at each expiration, and falls at each inspiration. Poiseuille observed the same phenomenon, under the same circumstances, in the large venous trunks in the thorax; but this phenomenon is not observed in the venous trunks situated at a distance from the thoracic cavity. We

(a) We assume the diameter of the aorta in man to be = 34 millimetres, and the column of mercury raised in the hemo-dynamometer = 160 millimetres.

can readily understand that, upon the dilatation of the thoracic cavity, the atmospheric pressure must compress the veins, and thereby, with the aid of the valves disposed in these vessels in a manner to prevent the reflux of the blood, assist the motion of the blood towards the heart. On the other hand, during expiration, the thoracic cavity contracts, and all the vessels contained in it are equally compressed. Indeed it has been experimentally demonstrated that the variations observed in the pressure of the blood, in the arteries and in the veins, correspond to the respiratory movements, and are no longer observed in the sanguiferous trunks situated beyond the precincts of the thoracic cavity.

The muscular contraction of the heart and that of the arterial walls are accordingly the principal motor powers of the sanguiferous circulation. The combination of these two forces, in the mechanism of the circulatory function, is so perfect that the movement by intermittent jets, caused by the alternate contractions and dilatations of the heart, is transformed into a continuous and regular motion by the force of elasticity with which the arterial walls are endowed.

Now, let us figure to ourselves a circular system, formed of tubes with elastic walls, and of different diameters; the two extremities or apertures of this tubular system open into two cavities separated from one another, and of which the walls possess the faculty of approaching one another and receding from one another, like the sides of a bellows; let us imagine this tubular apparatus filled with a liquid: upon rapidly closing one of the two cavities, by the depression of its movable wall, the liquid contained in that cavity will be propelled into the tube opening in it, and will on its own part propel the liquid column contained in that tube, and the movement of this column again will be rapidly communicated to the whole mass; at the same time the other part of the bellows opens, and the liquid in the opposite extremity of the tube precipitates itself readily into the dilated cavity. Were not the walls of the tubular apparatus elastic, these movements would be intermittent, and would stop the moment the bellows ceases to be open; but they become continuous from the elasticity of the walls of the tube, which exerts its action at the very moment the bellows closes, and continues to act during the whole of the time that the latter rests. Now, the heart performs the function which we have described here under the guise of the action of a bellows. The walls of the left ventricle approach one another and contract with great rapidity, which might even be accurately determined if we knew the precise direction of the contraction, and the exact amount of blood expelled. The capacity of the ventricle is thus diminished, and a certain amount of blood propelled into the aorta, the motion being thence imparted to the whole mass of the blood in the system. At this moment the arteries dilate, the right ventricle opens, and the blood rushes into it. Upon the cessation of the contraction of the left ventricle, the arteries contract to their original size, and this contraction supplies an additional propelling power.

The pulmonary circulation depends upon the same causes and follows the same laws as the general circulation.

DUMAS ON ORGANIC CHEMISTRY.

No. XXXI.

(Continued from page 587.)

THE MUSCLES.

The muscles constitute that which we ordinarily call the flesh of animals, and form the greater part of the mass of the body. They are detached organs, independent of each other; they are ordinarily covered by aponeuroses, and terminate in tendons which are attached to the bones. Their structure is somewhat complex, for, besides the muscular fibres which form their principal element, we also discover in them cellular tissue, adipose tissue, bloodvessels, lymphatic vessels, and nerves.

In a chemical point of view, fibrine constitutes the chief base of muscular tissue. But, from what we have just said of the anatomical composition of this tissue, we may readily understand that, independently of the fibrine, it must also contain the other materials of which the anatomical elements that we have above enumerated are composed. Now, it is impossible for the chemist to operate on the muscular fibre in a state of isolation, and, consequently, his analysis must embrace all the principles which enter into the composition of the entire mass of muscle, and which may be definitively classified as substances soluble in the different vehicles, or as insoluble bodies.

If the muscular tissue of the ox be desiccated, it leaves a dry residue, which may amount as high as 23 per cent.; but, should it be previously washed in water until this fluid becomes no longer coloured, the residue will scarcely be found equal to 17 or 18 per cent., and is then composed of fibrine and some insoluble tissues.

On washing finely-cut meat in pure water, until the latter ceases to be coloured, there remains a white, inodorous, and insipid mass, from which alcohol and ether remove a little fatty matter, and which, moreover, possesses properties almost identical with those of the fibrine obtained by beating the blood. It is, however, distinguished from it by some special characters. Thus, if, after having dried it, we again moisten it with water, it does not so easily regain its original softness as does fibrine. Further, if it be boiled with water, a portion becomes dissolved, whilst another part is rendered hard and remains insoluble; the filtered liquor assumes a jelly-like consistence. We have already seen that washed fibrine does not possess this property, and that the matter dissolved differs greatly from gelatine, both in its properties and in its composition.

Finely-cut meat, when treated by cold acetic acid, becomes partly dissolved, forming at first a jelly-like mass. The solution filters with difficulty, and leaves an insoluble deposit, composed in great part of the debris of the various vessels which the muscles contain.

Caustic potash, when aided by a gentle heat, dissolves washed muscular tissue. There remain, however, some debris which appear to belong to the cellular tissue, but which may be dissolved at a more elevated temperature. The acids partially precipitate this solution.

M. Chevreul has made some very important observations in relation to the extraction of the principles of the meat, and on the composition of broth: he made a decoction of 500 grammes of butcher's meat, deprived, as much as possible, of bone, tendons, and fat; the temperature was very gradually raised to the boiling point, and maintained there for five hours, taking care to replace the water according as it was evaporated. The decoction, when decanted and freed of fatty matter, contained:—

Water	988.570
Fixed organic matters, dried <i>in vacuo</i> at a temperature of 20° C. .. .	12.700
Soda	2.900
Potash	
Sulphuric acid, phosphoric acid, and Chlorine	
Phosphate of magnesia	0.230
Phosphate of lime	0.100
Oxide of iron	

1004.500

On introducing meat into a distilling apparatus, M. Chevreul found that several substances became volatilized, such as ammonia, a sulphureous product, a principle endowed with an animal odour, another principle possessing a scented odour, and traces of some acid very analogous to acetic acid.

M. Chevreul has extracted from the broth of meat a peculiar substance, to which he has given the name of *créatine*. This substance is obtained by treating with alcohol the aqueous extract of meat, after having desiccated it *in vacuo*; it crystallizes, by concentration of the solution, in straight, rectangular prisms; its

density ranges from 1.35 to 1.84. If it be heated, it crackles, parts with its water, melts without decolorizing, and then decomposes, at the same time giving out some ammoniacal products. One hundred parts of water, at 16° C., dissolve 1204 of *créatine*; whilst 100 of alcohol, having a density of 0.81, dissolve scarcely 0.05 parts, at a temperature of 15°. Sulphuric, nitric, and hydrochloric acids readily dissolve it.

The aqueous solution of *créatine* is not precipitated by chloride of barium, oxalate of ammonia, nitrate of silver, sulphate of copper, protosulphate of iron, subacetate of lead, or chloride of platinum.

When finely-cut meat is subjected to a strong pressure, there escapes a reddish-coloured liquid, having an acid reaction on litmus-paper, but which does not coagulate spontaneously. If, however, we take the still warm flesh of a recently-killed animal, and effect the division and pressure with great rapidity, the liquid obtained coagulates in the same manner as blood, and we find a small quantity of fibrine in the coagulum. To procure the liquid portion of the meat, we must exhaust it by small quantities of water. We thus obtain a red liquid, slightly acid, which contains some salts, albumen, and extractive matters. Its acidity is due to the lactic acid which is found there partly in a free state.

According to Berzelius, this liquid becomes cloudy at 50° C., and between 52° and 53° throws down a coagulum, of which the formation continues during some time; the supernatant liquid possesses the colour of venous blood. At 56° 6, the greater part of the coagulum is formed, and it will be found precipitated in a colourless state, even although the liquid may have been maintained for the space of half an hour at this temperature. At 62°, the coagulum acquires a red tint, but the liquid itself seems to lose nothing in the intensity of its colour. Above this temperature, the colouring matter becomes itself coagulated; but it is necessary to carry the liquid to the boiling point, to obtain a coagulum which can with facility be separated by the filter. In such case, the filtered liquid is almost colourless. The albumen, which is thus coagulated in a colourless state, possesses an acid reaction which is not removed from it by reiterated washings. We must always take the precaution of evaporating the solutions in which the albumen has been precipitated, should we wish to collect it entirely.

Berzelius on one occasion saw the liquid portion, from which the coagulum had been separated, become covered over with a pellicle on evaporating it at a temperature of about 85° C.; this pellicle was dissolved by the aid of heat in acetic acid, and thus formed a milky solution which was not clear at the end of two months; it was coagulated by hydrochloric acid. The substance found in this case by Berzelius possessed some of the properties of caseum. I have myself occasionally met with caseum in the extractive matters of the blood. It is easy to show that the acidity of the muscular fibre is due to the presence of lactic, or of some other organic, acid. We have merely to evaporate the liquid from which the coagulable matters have been separated, and to take up the residue by alcohol at 0.833. The alcoholic solution, on evaporation, leaves an extractiform matter, mixed with crystals of chloride of sodium, and which possesses a very manifest acid reaction. After incineration, this residue is found to be alkaline, which proves that the acid is in part combined with bases, and that it is of an organic nature. To isolate this acid, we pour into the alcoholic solution tartaric acid dissolved in alcohol, until all precipitation of the resulting tartrates ceases; when there will remain in solution in the alcohol hydrochloric acid, tartaric acid, and some other vegetable acid. This solution is then digested over pulverized carbonate of lead, filtered, and evaporated. The residue is dissolved in water, and the solution, freed from the excess of lead by sulphuretted hydrogen, is decolorized by animal charcoal; it furnishes, after renewed filtration and evaporation, a syrupy extract

which possesses all the properties of lactic acid. It is mixed solely with a little extractive animal matter.

The salts which exist in muscular tissue are very numerous; they are similar to those found in the blood and in the other products of the economy—that is to say, we here meet with salts having for their bases potassa, soda, lime, magnesia, and even traces of ammoniacal salts. These bases are combined with chlorine, phosphoric and lactic acids. We sometimes, though very rarely, also meet with sulphates.

The extractive matters of the muscular tissue have not yet been very perfectly studied, by reason of the difficulties attending their examination; in fact, they so greatly resemble one another in their general characters that we cannot completely isolate them, whether by the solvent vehicles or by the aid of those reagents with which they form insoluble precipitates. It is not only in the meat that we find these matters; they are also met with in the milk, the blood, the saliva, and even in the urine. Whatever their origin in the economy, they are invariably found to be identical in their chemical properties.

The extractive matters of the meat may be divided into three groups, according to their solubility in the different vehicles. When we act on the aqueous extract of meat by absolute alcohol, this fluid dissolves but one portion; dilute alcohol effects a second separation; and the residue of these two treatments is dissolved by water only. The alcoholic extract made with ordinary alcohol contains several azotized matters, some creatine, and lactates; it is to this extract that M. Thénard, and various other chemists after him, have given the name of *osmazome*. This name has even been extended to the azotized extractive matters which are met with, not only in animals, but also in plants.

Extractive Matters soluble in Absolute Alcohol.—On evaporating the solution of the extractive matters soluble in absolute alcohol, there remains a syrupy mass which retains its liquidity. It possesses a peculiar taste, at once sour and saline, and its odour resembles that of burnt bread; but, after keeping a very short time, it acquires a marked urinous smell. When heated in closed vessels, it decomposes, and disengages an odour of urine so characteristic, that one might be tempted to attribute to it an origin altogether different; eventually it becomes carbonized.

It is dissolved by water, which gives to it a yellow colour; the precipitate which this solution furnishes with bichloride of mercury and infusion of gallnuts, is but slight when compared to the quantity of matter dissolved. The same may be said with regard to nitrate of silver and acetate of lead. The subacetate of lead precipitates it abundantly. Oxalic acid throws down its lime. Nitric acid forms with it no precipitate of nitrate of urea, even after the lapse of several days; after an interval of a week, there appear some crystals of nitric. This alcoholic extract contains, besides the lactates, at least two azotized extractive matters, of which the one is precipitated by bichloride of mercury, and the other by subacetate of lead. We may separate them by treating the two precipitates by sulphuretted hydrogen, and taking them up again by water.

Extractive Matters soluble in Dilute Alcohol.—The alcoholic extract insoluble in absolute alcohol constitutes an opaque viscous mass, of a deep yellow colour. This residue is not wholly dissolved in alcohol at 0.833, which separates it into two portions,—taking up a yellow extractive matter, mixed with some salt, which is not destroyed by incineration. This extract, if heated till it commences to turn brown, disengages an odour similar to that of roast meat, and may thus be separated in great part from the salt which was mixed with it, by means of animal charcoal. The solution of this matter is, moreover, slightly clouded by infusion of gallnuts and by bichloride of mercury; but it is not precipitated by the neutral acetate of lead, nor by the protochloride of tin.

ORIGINAL CONTRIBUTIONS.

ON THE CAUSES OF DEATH AFTER SEVERE SURGICAL OPERATIONS.

By HENRY SMITH, Esq., Surgeon,
Late House-Surgeon to King's College Hospital.

(Continued from p. 573.)

From the cases I have mentioned, and the circumstances connected with them, I think we may conclude that irritation of the nerves, and subsequent irritation and inflammation of the parts supplied by them, are a frequent cause of death after operations on the arteries in the neck. It is impossible, however, to resist the conviction that their proximity to the heart renders an operation on them more doubtful and more hazardous: for this reason, probably, is it that, independent of other circumstances, operations on these arteries are so much more fatal than those performed on arteries of as great and greater magnitude, and surrounded by important textures.

The next case I have on the list is an operation on the external iliac for aneurism. This patient appeared to me to be a very bad subject for an operation: he bore the marks of severe and uncontrollable disease. During the operation the surgeon wounded the peritoneum. The patient died on the sixth day, apparently from irritative fever, lighted up by a low attack of erysipelas. Irritative fever is a frequent cause of death after operations on large arteries; but it is also a cause of death after operations of various kinds; so I shall not particularly consider this now, but defer it until I come to speak of other operations.

The fourth fatal case is the most interesting of the whole; it exemplifies well the two most formidable accidents which may happen after a ligature has been placed on a large artery, namely, secondary hemorrhage and gangrene. It was a case of ligature of the external iliac, by my friend Dr. Davies, of Hertford. The femoral artery had been first tied for popliteal aneurism. Eighteen days after this operation, secondary hemorrhage came on to such an amount that another ligature was placed just below Poupart's ligament; this restrained the hemorrhage. Five days subsequently, some appearances of gangrene showed themselves on the foot, and somewhat increased, but were eventually stopped by remedial measures. On the fifteenth day from the second operation, hemorrhage again recurred; the external iliac was then ligatured. On the fourteenth day, hemorrhage recurred, and subsequently returned. Gangrene of the limb and parts about the pelvis came on, but he lingered for two months after the operation on the iliac. The particulars of this very interesting case were published in the *Medical Gazette* at the early part of this year.

We have, then, here a case where death was brought about by two causes, either of which, separately, are most formidable accidents, and much dreaded by the surgeon; and I will now dwell shortly upon each of them.

Hemorrhage, that is to say, secondary hemorrhage, is a fertile source of danger after operations upon arteries. The surgeon feels the chief anxiety on that score. If we look through the records of surgery, we shall find that a large amount of patients who have died after these operations have perished from secondary hemorrhage.

If it take place to any great amount, it either quickly destroys the patient or renders it necessary that he should undergo another operation. The causes of hemorrhage are various, and not to be entered into in this place. It occurs in different degrees and at different times. The period at which it generally occurs is when the ligature is about to separate from the vessels; but this will differ according to the magnitude of the vessel which has been tied.

Operations upon arteries which would, in all other respects, have proved successful, have failed through this accident. Thus, in the two

cases in which the severe operation for tying the innominate was resorted to, hemorrhage caused death, but not until a considerable time after. Dr. Mott, of New York, performed the operation first. In his case hemorrhage took place on the twenty-third day; and it recurred several times, and destroyed the patient on the twenty-sixth day. Craëfe, of Berlin, operated in the other case. His patient was carried off by hemorrhage so late as the sixty-seventh day. Mr. Copland Hutchinson tied the femoral artery for aneurism; hemorrhage took place on the twenty-first day, and reduced his patient so much that he was necessitated to perform amputation.

Thus we see that secondary hemorrhage may occur a long period after the operation; at a period, in fact, when one would be justified in supposing that almost every other accident liable to cause death had been passed by.

Hemorrhage is more likely to occur after a ligature has been placed on an artery for aneurism, because the arterial system generally is more or less affected in this disease, and those healthy processes which take place when a ligature is applied to a sound artery cannot so readily be brought about. But hemorrhage is a much more rare accident now-a-days than it was before the time of John Hunter, when surgeons were in the habit of placing a ligature close upon the aneurismal sac; in fact, at that time the mortality was so great that Sir Astley Cooper has remarked, in his lectures, that it was considered quite a wonder for a person to be seen going about after the old operation for aneurism had been performed upon him.

Mortification of the part which is supplied with blood from the vessels tied is a not unfrequent cause of death. The records of surgery give many instances of this kind; the last case I have mentioned well exemplifies this. Every one is aware what an amount of mischief will result sometimes, when a part has been suddenly deprived of its accustomed supply of blood; not only when this supply has been cut off by the aid of the surgeon, but when, from some injury to the chief vessels, the circulation has been impeded or arrested. Thus it is one of the greatest rules in surgery that, whenever the chief vessels of a limb have been much injured, amputation should be performed to prevent the supervention of gangrene.

This accident is more liable to take place in some situations than in others. Thus it is more frequent in the lower extremity, for obvious reasons; and there is more or less likelihood of its occurrence, according to the situation in which a vessel is tied, and according to the freedom of anastomosis in the collateral branches. Let us take, for instance, the femoral artery. Gangrene of the limb is much more likely to ensue after ligature of the common femoral than of the superficial femoral. The ligature on the former stops the circulation in the profunda, which chiefly supplies the thigh and nourishes it; whilst a ligature on the latter only commands the circulation in the superficial parts, and leaves the profunda free.

Mortification, then, is a result of operations on arteries which the surgeon has a well-founded dread of, for, if it occurs, the case is generally hopeless: death will either soon take place, or there will remain the only alternative of amputating the part at a point above the ligature, which, in such circumstances, is a proceeding fraught with extreme danger.

There is yet another cause of death after ligature of arteries, in the abdomen particularly, and that is common to all operations performed on that part, namely, peritonitis. This has occurred after ligature of the external iliac, but I believe not frequently. In the well-known instance of Captain Seaton, when Mr. Liston placed a ligature on this vessel, death ensued in a very few hours from peritonitis, although no damage was done to the lining membrane of the abdomen.

I now come to the second series of cases—those in which the operation for lithotomy was

performed. I have notices of sixteen cases, of which four proved fatal. We all know that the operation of lithotomy, even at this day, when it is carried to such simplicity and perfection by such surgeons as Liston, Fergusson, and Key, is attended with considerable danger. An operation of great magnitude, and performed upon delicate and important parts, liable to inflammation and all its bad consequences upon the slightest injury, it requires the strictest knowledge of anatomy, and the greatest coolness and perseverance on the part of him who performs it. Nothing has struck me so forcibly as being true, as an observation once expressed to me by the distinguished Professor of Surgery at King's College: that it is particularly in the operation of lithotomy that the surgeon cannot estimate beforehand the extreme difficulties with which he may be overtaken during its performance.

Of the four fatal cases, I witnessed three, and know the particulars of each; and they will be found highly interesting. The first was one where Mr. Fergusson performed the operation in a most admirable manner.

The subject of it was an old man past seventy; the operation was done in Mr. Fergusson's ordinary manner, with the knife, and a small incision in the neck of the bladder. This man did not die until several weeks had elapsed; but the cause of death was one which not unfrequently happens, although there were peculiarities in the case. He appeared to labour for some time under severe irritative fever, having for the first week or ten days gone on well. The wound had nearly healed up, but it opened again; feces and urine passed through it, and he died with all the symptoms of severe irritative fever. On inspection of the parts after death, a large abscess was found between the rectum and bladder, and an ulcerated opening was found in the former, which fact accounted for the feces passing by the wound. Mr. Fergusson, in some clinical remarks, observed that the ulceration and suppuration were caused by the urine setting up some unhealthy inflammation.

This case is a curious and remarkable instance of death caused by the chief danger after lithotomy, namely, urinary infiltration. The particulars of the case were published in the *Lancet* for 1846.

We can readily understand how infiltration of urine may cause a serious result, and how easily it may take place, when we remember the mischief it causes in the tissue of the perineum and scrotum from rupture of the urethra, and when we call to mind the parts that are cut in the operation, and the great likelihood of escape of urine into the tissues around. This accident—so much to be feared by the surgeon—may depend upon causes which may be obviated. Thus it may depend upon the nature of the incision into the neck of the bladder; and much has been written upon this subject. Some eminent surgeons have recommended a very free incision. Amongst these is Mr. Samuel Cooper, who has written an interesting paper on the subject. He says that there is no more danger of urinary infiltration after a free incision than after a small incision. On the other hand, many say that a very free incision is accompanied with this and other dangers. The celebrated Scarpa recommended a very limited incision. The incision made by Mr. Fergusson in the neck of the bladder is generally very small; and I believe Mr. Liston advocates the same plan of operating. I think we may reason with propriety that there is less danger attending a small incision.

Urinary infiltration may also be favoured if the external wound does not correspond to the internal; for instance, if the former has been made too high up, we may expect that the urine would not have a free passage, would collect at the bottom of the wound, and cause mischief. There can be no doubt that these matters have in some degree an influence over the result of an operation.

There are several other causes of death after lithotomy. I have already spoken of the formidable nature of the operation, and of the diffi-

culties and dangers which surround the surgeon. In some cases none exist, or they are slight, and the patient, when under the hands of a practical operator, is not kept more than two or three minutes upon the table; but, on the other hand, some unforeseen difficulties may present themselves, which will either render the operation long, painful, and bloody, or will entirely overcome the efforts of the surgeon. It is not to be wondered at, then, that, under these circumstances, the patient should die purely of the shock caused by the proceeding.

The second case is an example of this.

Mr. Fergusson performed the operation upon an old man. There was unusual difficulty in all the steps of this operation. During its performance I could see the difficulties which the operator laboured under, but it was not until after death, when I saw the parts displayed, that I could so well sympathize with him in his difficulty. There was a great depth of substance, even for the longest finger, to get into the bladder. The outlet of the pelvis was unusually narrowed by the extreme size of the rami of the pubis and ischium; and, to crown the difficulty, the stone was large, flat, and oval—most awkward for easy removal. Under all the circumstances, the operation was much prolonged. Mr. Fergusson found it necessary to use the knife frequently, and the forceps were introduced and withdrawn many times by that skilful and persevering surgeon before the stone could be extracted; great bruising of the parts must necessarily have been the consequence; great pain and irritation must have been felt (and this was previous to the introduction of ether in surgical operations).

This poor man suffered severely; a great shock to the system had taken place, and, notwithstanding every care, he gradually sunk, and died on the third or fourth day after the operation, no inflammation nor other mischief having occurred in the pelvis or abdomen.

We see, then, that shock may cause death after lithotomy; this is common after all severe operations, and we cannot wonder at its occurrence after this severe proceeding, when we consider the difficulties and dangers it presents.

The third fatal case I have to particularize was still more interesting and instructive than either of those yet mentioned. In this case death was chiefly owing to a naturally irritable and nervous state of constitution, excited and perturbed by a severe operation.

As I have before mentioned, the result of an operation is greatly influenced by the constitutional endowment at both of body and mind. A naturally vigorous body and firm mind are much in a man's favour; on the other hand, an irritable and nervous state of both are bad for an operation. In such conditions, an injury to the body will always cause a corresponding amount of disturbance; and, when once set up, it requires the greatest skill on the part of the surgeon to obviate, and there is no knowing where it will end. Every one who has seen much of injuries and operations must have noticed how surely any shock to a naturally irritable system will produce symptoms the most serious, and the most difficult to overcome by remedial means. Extreme restlessness, sleeplessness, delirium, tremours, and tetanus are the most prominent of them; and these, as every one who has had the after-treatment of operations knows, are most difficult of control, and most likely to prevent a successful termination of an operation. We may, then, expect to find these unfavourable symptoms occur after such a severe operation as lithotomy. The case I am about to mention is an example.

The patient was a medical man, aged fifty-two, of a naturally nervous and irritable temperament, and belonging to a family possessing the same temperaments. I assisted at the operation, and partly had the care of the case afterwards until death took place. The operation was easily performed, but some deep veins were wounded, which caused considerable, but not extensive, hemorrhage. In the course of two or three days great irritation came on about the neck of the bladder, rendering him restless and nervous. He had been subject

to piles, and now this local irritation near them caused a great aggravation. They became large, swollen, and inflamed, and added greatly to the irritation. Restlessness, apprehension of danger, and want of sleep, were the consequences; the local irritation was somewhat relieved by anodynes in enemata, and by the mouth, but only for a time. He went on day after day, sometimes being calmer and quieter for an interval; but he again got worse. Sleep could not be procured, nor the restlessness be calmed. On the fifteenth day hicough came on, and persisted with great violence; the pulse was high, and the tongue furred, but it was evident it was merely one of the links in the chain of nervous symptoms which was pulling him to pieces. Vomiting supervened. These symptoms remaining almost to the last wore him out, and he died on the eighteenth day from exhaustion. On the examination, after death, there was, as we expected, not the slightest trace of inflammation of the peritonæum, or mischief about the wound. This latter looked healthy up to the last, and it was found to have been healing favourably.

In this case the local irritation of the wound, and the additional irritation of piles, caused, on a naturally susceptible frame, such an amount of excitability of brain, diaphragm, and stomach, as produced the sleeplessness, hicough, and vomiting, which could not be restrained, and which ultimately destroyed him.

Inflammation of the peritonæum may arise after lithotomy and destroy the patient. We know how apt this is to occur when the contents of the pelvis or abdomen are meddled with. The surgeon is naturally anxious on this score after he has performed the operation of lithotomy. Inflammation of the kidneys may also take place after lithotomy. The surgeon has a well-founded dread of suppression of urine occurring after it. Hemorrhage sometimes occurs, and proves fatal in this as in other operations, but fortunately it is rare.

Mr. Crosse, of Norwich, mentions a fatal case from this cause; the bleeding took place from the internal pudic artery. Sir Benjamin Brodie also relates a fatal case; the bleeding took place from the veins about the prostate. The artery of the bulb, if large, might throw out a sufficient quantity of blood to cause death. It is impossible, probably, to avoid these accidents in some cases; yet, by carrying the knife neither too near the rami of the pubis, nor too high up, the wounding the pudic or the artery of the bulb may be prevented; but, notwithstanding the knife may be used with the utmost skill and caution, hemorrhage may take place from an irregular branch or branches, which are found here as well as in other parts. It is right for the surgeon when he undertakes this operation to recollect the possibility of its occurrence, otherwise he may meet with difficulties which may annoy him.

(To be continued.)

ERRATUM in Mr. Henry Smith's paper in the *Medical Times* of Sept. 11:—Eleventh line from the bottom of the first column, for *correct*, read *carried*.

THE PHYSIOGNOMY OF DISEASES OR SEMEIOTICS IN THEIR ASSIMILATIVE CHARACTERS.

By GEORGE CORFE (Author of "A Popular Treatise on the Kidney," &c.), of the Middlesex Hospital. (Illustrated by Portraits of Cases.) (a)

ARACHNITIS.

The great difficulty which the most eminent surgeons encounter in the formation of a just diagnosis in injuries of the head, and the obscurity attending those fatal symptoms which ordinarily follow such lesions, are chiefly witnessed in large hospitals. The above disease is rarely met with, as an idiopathic affection, in these institutions; and I shall, therefore, take the present opportunity of tracing a marked instance of traumatic arachnitis, which terminated fatally

two days ago, and the *post-mortem* examination of which took place yesterday.

The case was the following:—Jas. Meaders, aged fifty-one, admitted May 8, under Mr. Shaw, with a slight wound over the *left* eyebrow, with the frontal bone denuded, and fractured radius, near its humeral extremity, on the right arm. Two days after his admission, he had a sharp attack of erysipelas, extending over the head, face, and neck, which, however, passed away, and he was apparently convalescent from it in ten days. On the expiration of a fortnight from this period, Mr. Shaw observed that he was slightly deaf in the right ear; that there was, moreover, partial hemiplegia on the same side; and that the two halves of the face did not quite correspond in symmetry. As the erysipelas had chiefly occupied the right side of the head and face, it was supposed that this slight distortion did not arise wholly from cerebral disease. However, the house-surgeon, Mr. Dixon, hastily summoned me to see him on the 8th of June, in consequence of a severe fit in which he was then struggling. The face, owing to the former erysipelous inflammation, was blackened with turgidity, and presented the aspect of a man who had been strangled or drowned. The countenance was a ghastly figure, both in appearance and its features; there were hemiplegic twitchings and convulsive throes of the right half of the body. There had been increased deafness and impeded deglutition for two or three days prior to this fit. The tongue was not protruded with ease, and he could not, or would not, answer to our questions so readily or so easily as he had done. These symptoms led me to suppose that either the cerebellum or pons varolii, or medulla oblongata was suffering from some injury which it had received in the *contrecoup* to the blow on the forehead. Mr. Shaw did not take this view of the case, but regarded the symptoms as the result of active inflammation, beneath the dura mater, of the wound, and that the impaired functions, as it seemed, of the seventh and ninth pair of nerves were the effect of the erysipelous swelling. The immobility of these muscles, he conjectured, resulted from the oedematous stiffening which cellular inflammation had left in its train. The accuracy of this shrewd and, to my mind, doubtful diagnosis was fully borne out by the *post-mortem* examination. The jugular was now opened, but only a few ounces of dark blood flowed; the temporal artery, and, a vein in the left arm, were successively tried, but not more than seven ounces of blood could be obtained altogether. The pulse rose to 120, but diminished in power, the respirations became deeper and less oppressed, and the ghastly appearance of the countenance gradually subsided. A turpentine enema was administered, and, as he already had taken repeated doses of calomel every four hours, it was deemed unnecessary to alter this part of the treatment. On the following day he was much rallied, but the improvement was of short duration, for in the course of the same afternoon he had another and more severe fit, and sunk in a few hours afterwards.

Post-mortem Examination Eighteen Hours after Death.—*Head.*—The frontal bone was slightly blackened; purulent matter oozed out from beneath the scalp around the wound. The calvarium being removed, a gush of lymph and whey-like serum escaped from beneath the dura mater on the right side. The whole of this hemisphere was coated with a thick layer of coagulable lymph, and the portion of dura mater immediately opposite to the wound was studded with spots of purulent matter, and the lymph on the cerebral surface, at this point, was unusually thick and firm. The substance of the brain was softened, also, in the anterior lobe of this hemisphere. The arachnoid and the whole cerebral matter on the left side, were perfectly healthy. There was no effusion or disease in the pons varolii, or medulla oblongata, only that the lymph, on the right side, extended as far as the base of the brain.

The following fatal case of idiopathic arachnitis, which has recently occurred, also may

tend to illustrate the difficulties which surround this class of cerebral diseases. The symptoms, it will be observed, were quite of an opposite nature to the last-cited case, and yet the diagnosis was found to be a correct one by the *post-mortem* examination. I attribute this circumstance, in a great measure, to the fact that, in all acute diseases springing up in an idiopathic form, especially where those diseases attack organs that are essential to life, the recognition of a malady, both in its rise and progress, may be made through the study of the physiognomy, although the patient may be quite insensible, or, at least, unable to furnish us with any information about his sufferings.

ACUTE MENINGITIS—HYDROCEPHALUS—SOFTENING OF THE SPINAL CORD OPPOSITE THE SECOND AND THIRD CERVICAL VERTEBRÆ.

Peter Groves, aged ten, errand-boy at a fishmonger's, was admitted, under Dr. Thompson, June 15.

Countenance extremely heavy, dull, and of a dusky colour; brows knitted; eyes half closed; eyeballs prominent, and rolled upwards; pupils dilated, especially the right; slight twist of the mouth, and a flatness of the left half of the face; left angle of the mouth drawn downwards; nostrils pinched up as in sniffing, and their angles depressed downwards and slightly outwards; feeble in the right arm and leg; skin covered with a dirty, greasy sweat; pulse full and slow; cannot protrude his tongue, or give any account of his sufferings, but he screams piercingly when moved, as though he was suddenly alarmed or frightened; and if he is roused for a moment he turns on his side, and doses off immediately; scalp hot and flushed; bowels confined.

The mother stated that ten days ago he came home from his situation, and was unusually drowsy, but in two or three days more, after the action of some aperient medicine, he rallied and went out a little, but relapsed, and he had been lying at home constantly dosing ever since. She also observed that he could not hold his cup to drink with his right hand, whilst at tea the preceding day.

The doctor treated this case actively, by ordering the head to be shaved, and *c.c. ad 3vj. pono aures. Hydr. chlor. gr. ij. 6tis horis, ol. ricini 3ss. stat.* Notwithstanding the utmost antiphlogistic measures, the child survived only six days after his admission.

Post-mortem Examination.—*Head.*—Acute inflammation of the arachnoid over the base of the brain only, with layers of lymph, chiefly around the posterior lobes; ventricles distended with clear, pale serum. The medulla oblongata and spinalis, as far as the fourth cervical vertebra, was not only acutely inflamed, but there was ramollissement of the whole portion of nervous matter in this situation. No disease in the other two cavities of the body.

The portrait of this case forms one of the series of the collection in my possession.

CLASS I.

Division II. Cerebral Asphyxia in Stupor; Countenance livid.

From Narcotic poisons.

Coma.

Hepatic disorders.

Renal degeneration.

Intoxication.

Syncope (hemorrhagic).

Facial paralysis.

NARCOTIC POISONS.

Of these cases, *opium* in substance, or *laudanum*, the most common of all the poisons taken for a suicidal purpose; essential oil of almonds, monkshood, foxglove, oxalic acid, veratrina, and hellebore, have come under my notice during twenty years' hospital practice. With respect to the results of poison by the first of the above-mentioned narcotics, I may here remark that I have never been able to satisfy myself that the smell of laudanum could be distinctly traced in the matters brought off the stomach by the pump, in cases of narcotism by this drug; which nega-

tive evidence is contrary to what is asserted in some toxicological works. In the first of these poisons only is the pupil contracted, whilst in all the others the iris is dilated.

It is quite unnecessary to enter into any scientific details upon the subject of poisoning by the narcotic drugs above mentioned, as these matters are treated of in the works on medical jurisprudence and toxicology; besides, I have only enumerated those poisons which have been taken intentionally or otherwise, and which have actually come under my own observation, and am now only desirous to allude to the subject practically, and that for the benefit of the younger branches of the profession.

Now, it is commonly stated by toxicological authors, when treating upon the subject of poison by laudanum, that, after the stomach has been washed out by the pump, coffee or green tea should be administered. This practice is really quite useless—nay, I believe is very often prejudicial. The stomach is only irritated by it, and neither beverage has the effect of keeping the nervous system in a state of insomnia. There is, however, benefit to be derived from constant, persevering, but moderate exercise in the open air; though the patient, at the outset, may be scarcely able to drag one leg after the other, yet have I seen such an individual led out into the hospital garden, supported by two strong men, and what with an occasional bastinado over the buttocks, in the form of a long, flat, and thin splint, pulling the hair, dashing the face with cold water, and then smartly rubbing it dry with a rough towel, and again goading the patient on to walk—I say I have witnessed recovery from the very worst forms of narcotism by laudanum under such rough and apparently unfeeling treatment, whilst tea, coffee, and such like fluids, have been rejected as fast as they were swallowed. If a third person does not follow in the rear whilst the patient is walking, and lay on pretty smartly over his glutei from time to time as he flags and drags along, he will not be kept sufficiently roused to walk at all, and, when once he gets off his legs, you have an extraordinary difficulty to get him up fairly in walking order again.

But it cannot be too strongly urged on the attention of the profession, that all this unsatisfactory, rough, and wearying treatment can be wholly dispensed with by the employment of the electro-galvanic battery. The singular effect of this extraordinary agent is well described in a case recently published by my excellent colleague, Mr. James, the assistant-apothecary, who perseveringly employed it in a most aggravated form of narcotism, with perfect success. The patient, a female, was roused up to complete consciousness in one hour from the time that this remedial agent was in operation.

Two days ago, also, a case of poisoning, by muriate of morphia, was submitted to the influence of the battery. She had taken five grains of the salt six hours before the police brought her to the hospital. There was no probability of recovery; however, the effect of this agent was most striking. On admission the countenance was of a ghastly, livid, and death-like expression; lips tumid and blackish; pupils greatly contracted; extremities mottled, blue, and cold. The respirations were two in a minute before we commenced, and the pulse 100. When the pump had emptied the stomach the pulse rose, under the influence of the battery, to 120, but in another quarter of an hour it sank to 80, and soon ran down to 60. All hopes of her surviving began now to diminish; however, the respirations were equal and deep, so long as the battery was at work upon the patient, but the moment it was suspended the breathing altered in its character. At the expiration of one hour we were induced to remove her from the chair in which she sat to the couch, in order that greater facility might be afforded to the operators; however, in so doing, the wire of the battery became displaced, and its action was necessarily suspended for three or five minutes; the alteration in the breathing, pulse, and countenance was sudden and marked. In

less than eight minutes more she ceased to breathe, and the pulse was gone from the wrist.

On examination of the body, the brain was simply gorged with dark blood; this fluid had no where coagulated; it was black and thick in the left side of the heart, and there was a colourless mass of fibrine in the right ventricle. The stomach was merely ecchymosed in one spot, but all the other organs were healthy.

A very striking and successful case of narcotic poisoning, treated by means of electricity alone, has been published by an intelligent house-surgeon, Mr. Hensley, who, with myself, kept up the administration of electric sparks, unremittingly, during five hours, when consciousness suddenly returned, and the patient rapidly recovered.

There is another point that I must here advert to in this part of my subject, and it is one of the greatest practical utility. In the after treatment of all cases of poison, but especially in those of the mineral poisons and oxalic acid, toxicological writers do not lay sufficient stress upon the importance of keeping the patient in a state of complete starvation during the first two days after the poison has been taken. If a medical practitioner has an acute case of iritis under his treatment, he excludes every ray of light from the inflamed organs, so also the surgeon who has a sprained ankle or fractured limb to treat, orders the injured part to be kept in the most perfect state of quietude; as, therefore, the light, which is the natural stimulus to the iris whilst in health, becomes an injurious agent under disease, so, in like manner, the inner surface of the stomach is stimulated by the presence of food; but when this organ is acutely inflamed, the judicious practitioner is not only desirous of lowering this gastric inflammation, but he is careful not to allow any substance to pass into an organ, the direct tendency of which would be to increase that inflammation by the stimulating process of digestion.

A large number of cases of poisoning by oxalic acid have entered this hospital, in which no untoward symptoms have arisen, and, consequently, no fatal results have followed. I attribute this circumstance to the measures that have been invariably adopted in such instances. It is somewhat distressing to a patient to suffer from urgent and intense thirst, and yet not be allowed the gratification of swallowing a pint of liquid, as tea or toast and water, every ten minutes or so, but to have some bland fluid, as barley-water, served out to him in teaspoonfuls, every half hour; yet such is the treatment that I strictly enjoin during the first two or three days after the stomach has been emptied of its deadly poison.

In all these cases the most perfect abstinence is rigidly adhered to, by strict injunctions to the nurse, and even, as is necessarily the case here, to the patients of the ward also, lest the earnest importunities of the suicide to obtain some food should induce the neighbouring persons to give it. I am certain that this point is most important; and, therefore, I would caution my junior readers not to allow such a patient more than one pint of barley-water, and this to be sipped at, and so consumed in the course of a day and night, for the first two days, in such cases of poisoning.

Many years ago I casually heard, from one of our more observant nurses, that all the leeches applied to persons who had taken oxalic acid died soon after they fell off. Knowing the solubility of this acid in the stomach, I did not doubt the fact; however, I was not satisfied until I had watched the animals myself; and I have seen them drop off the surface, curl, and wind about, shrivel, and die in a short time.

But since the above period I find that Professor Christison, in his admirable work on "Poisons," notices the same fact, which was communicated to him by a medical gentleman. But I am inclined to think that the professor will ascertain for himself, from intelligent nurses, that these animals die very soon after they fall off from the patient. I am not aware that this singular effect results from any other poison which may be taken into the system.

(To be continued.)

PROGRESS OF MEDICAL SCIENCE.

ACADEMY OF SCIENCES.

Meeting of Sept. 14; M. BRONNIANT in the Chair.

TYPHOID FEVER.—M. Lafont-Gouzi, of Toulouse, forwarded to the academy a paper relative to the recent communications of Professor Serres, on the subject of typhoid fever. The treatment from which M. Lafont-Gouzi had derived the greatest benefit consisted in the exhibition of calomel in doses of six grains daily.

TREATMENT OF PURULENT ABSORPTION.—In order to prevent, or to arrest the progress of, purulent absorption from wounds, M. Gouyon recommends the cauterization of such wounds with a solution of nitrate of silver (3j. to 3j.). The statement being, however, merely an assertion unsupported by cases, it is impossible, for the present, to form a positive opinion of its value.

ACADEMY OF MEDICINE.

Meeting of Sept. 15; M. BROIN in the Chair.

LITHOTRITY AND LITHOTOMY.

M. Velpeau remarked that it was impossible to admit M. Civiale's assertion, that relapses were more frequent after lithotomy than after lithotripsy. The researches in the bladder were easy and complete after cutting, whereas it was very difficult after crushing to be certain of having removed all the fragments; besides, M. Civiale's own statistics were in contradiction with his opinion. Thus M. Civiale mentioned 51 cases of relapse out of 600 cases of lithotripsy, and 42 only out of 1000 cases of lithotomy. M. Civiale attributed the fatal termination of cases of crushing to the clumsiness of the operators, and seemed to assert that he alone could perform the operation with satisfactory dexterity. This might be a convenient argument, but it was a strong one against the method advocated by M. Civiale, for when that learned academician had paid, as some day he must, his debt to nature, what would become of a method which was safe in his hands only? This was however, in M. Velpeau's opinion, a calumny against lithotripsy; many names were in the thoughts of all members who were fully competent to operate. On the other hand, the operation was not in itself so difficult as M. Civiale represented it to be: its perils did not arise so much from its complication as from the organic condition of the patients who submitted to it. Finally, M. Velpeau would say, that the cases to which lithotripsy was applicable were not as yet properly specified; that it was not yet decided when that operative method should be preferred to lithotomy; that its success had been much exaggerated; and that it presented as much danger as cutting in those cases in which cutting was perilous.

M. Amussat, after some general remarks, endeavoured to solve the following questions:—What are the cases to which lithotomy or lithotripsy are applicable? Is there any general method applicable to all calculous patients? Is lithotripsy susceptible of much improvement? The two operations could not be indiscriminately performed: this was an assertion suggested by common sense, and proved by numerous facts; but, although this opinion was very generally subscribed to, still, in practice, it seemed that many patients were cut who might have been operated by lithotripsy; surgeons too fond of the knife feigned to consider this mode of treatment as tedious, and fit only to be employed by specialists; on the other hand, lithotriptic surgeons were also exclusive in their opinion, and applied their method to cases which should be treated by the knife; hence on both sides an equally unjust exaggeration. M. Amussat was, however, of opinion that lithotripsy should always be first thought of, and that lithotomy should be resorted to only in those cases which it was not possible to submit to the crushing instruments. As to the progress of lithotripsy, M. Amussat considered that a very great benefit had been derived from the inhalation of ether, which permitted to pro-

long each operation without pain, and to rid the patients in a much shorter time than heretofore of their concretions.

M. Sigolas then requested permission to read a paper on "The Choice of an Operation in cases of Vesical Calculus."

The choice of an operation in cases of this description was the real question at issue in the present debate. It was the only practical one, and the only one which the author intended to examine. The only general answer which could be made was of so very comprehensive a nature as to be entirely without value, and what M. Sigolas merely proposed to himself was, to lay before the academy the opinions which had resulted from twenty years' observation. The conditions which rendered lithotripsy absolutely impossible might be referred to the concretions, to the bladder, the urethra, or the prostate gland. With regard to the calculi, their size or their extreme hardness only might interfere with the operation; their number could not be considered as an objection, because each stone might be isolately crushed and removed in succession. As to size, M. Sigolas had crushed concretions of twenty-five and even twenty-seven lines in diameter; but this appeared to the author to be the extreme limit of magnitude of calculi to be destroyed by the act of the lithotriptist. The hardness of the stone had seldom proved an insurmountable obstacle to crushing, except when coupled with excessive volume. In such cases M. Sigolas had remarked that the stones were composed almost exclusively of lithic acid, and had formed fifteen or twenty years previously to operation. Phosphatic concretions were readily destroyed by simple pressure; and calculi of oxalate of lime yielded generally, without much difficulty, to percussion. The bladder interfered with lithotripsy only by violent and too frequent contraction, by a shrinking of the walls of its cavity which left no room around the calculus for the action of the instruments; however, this could be looked upon as an obstacle only when the calculi were of a large size and of considerable hardness. Besides, in such cases much advantage might be derived by placing the patient in a warm bath, and endeavouring afterwards to prevent him from voiding urine, in order to distend the vesica as much as possible. Paralysis of the bladder in no instance became an obstacle to the operation; on the contrary, the division of the stone was more readily effected; and, although it was afterwards necessary to use mechanical means for the removal of the fragments, this was now rendered a very easy matter by the use of the improved instruments in the hands of all surgeons, and particularly with the assistance of injections. But the existence of lacunae in the bladder was an anatomical circumstance most unfavourable to the safe performance of lithotripsy; it might even altogether preclude the possibility of employing that method. The concretions being in some cases almost altogether incarcerated in these lacunae, or the fragments becoming after the operation lodged in these cavities, lithotripsy became always uncertain in its results, and sometimes impossible. Two years since, M. Sigolas had presented to the academy the history of an old man who was affected with a calculus lodged in one of those pouches; the case had terminated favourably; but, in another instance of the same sort, M. Sigolas had been obliged to have recourse to hypogastric cystotomy—an operation which was performed with the assistance of the ethereal inhalation, and which had a most happy issue. Tumours within the bladder rendered lithotripsy difficult, but never absolutely impossible. Cystitis became an obstacle only by causing violent contraction of the bladder, and by rendering the use of instruments exquisitely painful. *Hypertrophy of the prostate*, now-a-days, constituted no insurmountable obstacle to crushing; and this was due to the introduction of curved instruments into that branch of practical surgery; strictures of the urethra constituted only a temporary obstacle, which might in a few weeks be readily vanquished. A professor of the school of Montpellier had proposed in cases of severe

stricture to make an opening into the urethra behind the constriction, and to operate for lithotomy by introducing the crushing instrument through the incision. The commission of the academy had not sanctioned this practice; and M. Sigolas adopted entirely the opinion entertained by the commission, because a few weeks' perseverance might always permit the surgeon to overcome the difficulties presented by a stricture, however severe. The diseased state of the ureters, of the infundibula, or of the calyces might certainly diminish the chances of success of the operation of crushing a calculus, but did not in any way interfere with the surgical process. Lithotomy was easier in women than in men; and with regard to age, M. Sigolas had operated with success even in the most tender infancy, for instance, in a child aged twenty-three months, who had been presented to the academy. Thus the excessive size or hardness of the stone, its deep and tight incarceration in the vesical lacuna, and the obstinate retraction of the bladder were the only absolute and insurmountable objections to the performance of lithotomy, and the only circumstances which rendered cystotomy necessary. But it did not follow, from the mere practicability of lithotomy, that it was proper to adopt that method of removing the stone. The mechanical possibility of an operation was separated by a wide chasm from the expediency of its performance. In this respect, lithotomy was submitted to the general rules of surgery, and the discrimination of the cases to which it might with propriety be applied demanded from the surgeon as much knowledge, tact, and prudence as any other surgical problem. M. Sigolas would now endeavour to separate the cases which required one method from those in which the other was indicated.

Taking into consideration the size of calculi, M. Sigolas recognised four sorts: the *small* concretions, the diameter being under six lines; he called *middle-sized* those of from ten to fifteen lines in diameter; *large*, those concretions of fifteen or twenty lines; and *very large*, those calculi of more than twenty lines in transversal diameter. All the small concretions should be, in M. Sigolas' opinion, crushed; the same might be said of middle-sized stones, were it not for certain conditions of mobility and of general health which might render immediate extraction a matter of imperative necessity, as, for instance, an apopleptic predisposition, together with cystitis and frequent efforts of excretion. For large stones, again, lithotomy was preferable to cystotomy, provided the calculi were fragile as recent concretions, particularly phosphatic, generally were, and if the state of the kidneys or ureters offered no counter-indication. As to the very large stones, a distinction should be established. If they were formed of phosphatic salts they might readily be crushed; but calculi of uric acid above 20 lines in diameter were usually of extreme density; their destruction required considerable time, and their angular fragments often occasioned in the bladder great irritation, and too frequently sympathetic excitement of the kidneys and digestive tube. In such cases M. Sigolas thought that cystotomy was safer, but it was not always in the power of the surgeon to persuade the patients to have it performed in place of the apparently singular operation of crushing. Calculi of oxalate of lime seldom acquired so considerable a size, and were destroyed without much difficulty; besides, they were always observed in very young subjects, and were very rarely attended with complications. The number of the concretions, if their size be small, should not prevent lithotomy; and it was of very uncommon occurrence to meet with several very large stones in the same bladder; but if such a case was observed, lithotomy would certainly not be applicable.

Obstinate inflammation of the mucous membrane of the bladder, attended with contraction of the viscus, constituted a counter-indication to crushing. The counter-indication was still more evident if the urine contained habitually pus or blood, or if an ulceration or an organic disease

was recognised in the vesica. The frequent introduction of instruments would increase the local damage, and might even endanger the life of the patient. A tumour of an indolent nature within the bladder, not containing much blood, was not an absolute obstacle to crushing; but if the calculi were numerous or hard, cystotomy would be preferable. When lacunae were present in the walls of the viscus, cutting would be almost always a safer plan of treatment than lithotomy; but disease of the prostate or strictures of the urethra should not cause this mode of destruction of calculi to be abandoned.

The various disorders of the kidney, ureters, calyces, &c., were most unfavourable circumstances for the success of one or the other method; but if one of the two should absolutely be chosen, M. Sigolas would recommend cystotomy.

Sex or age constituted no obstacle. M. Sigolas had operated by crushing in twenty-six children, who all were cured with the exception of one, who was affected with caries of the humerus, and entered into Hospital St. Louis for the treatment of this malady. Cystotomy was afterwards performed by M. Guersant, and the child ultimately recovered. In several of these children, however, lithotomy was attended with much difficulty, and required great care and patience, chiefly on account of the narrowness of the anterior part of the urethra, and the comparatively great dilatation of the deeper portions of the duct, into which large fragments often became impacted.

In conclusion, M. Sigolas stated that to a first class of calculous patients crushing might be advantageously applied; in a second class cystotomy presented less peril, or was alone applicable; and to a third series all operations should be set aside. The progress of lithotomy, and its growing popularity, enlarged daily the numbers who composed the first series at the expense of both others; and a day would most probably come when crushing would be used in almost all cases, and cystotomy applied only to a small number of exceptions.

Meeting adjourned at five.

D. McCARTHY, D.M.P.

TO CORRESPONDENTS.

THE MEDICAL TIMES may be procured by an order on any Newsmen or Bookseller, or it will be sent direct by post from the Office of the Medical Times to Subscribers sending by a Post-office order, directed James Angerstein Carfax, or an order on some party in town, One Guinea IN ADVANCE, which will free them for twelve months. Half-yearly Subscription, 13s.; Quarterly, 6s. 6d.

A Constant Reader, Devonport.—The article may be obtained at Mr. Button's, chemist, High Holborn.

T. B.—The subject will be again discussed at an early opportunity.

Mr. Samuel Seaton.—The case of injury to the spine is under review, and will probably be inserted in an early number.

Mr. Norris, South Petherton.—We are sorry for the mistake in the name. The communication will probably be inserted next week, when due attention will be paid to the intimation.

M. D., Brixton.—The communication has been received, and a full answer will be given to it next week.

A Union Surgeon.—The facts would be more clearly understood if thrown into a tabular form.

A Country Surgeon.—The National Institute has published its annual list, which may be obtained on application to the secretary, Mr. Ross, Hanover-square Rooms, Hanover-square.

Philo, Dublin.—The information sought will be found in the Students' Number, published last week.

S. J.—We do not wish to interfere in professional misunderstandings. A little forbearance would oftentimes be the means of avoiding many unpleasantnesses.

Senex.—The case does not present sufficient interest for publication.

L. F. B. can learn his profession very well at the place he names. It is not the place, but the student—not the price, but the studies.

True O. writes us very just remarks in a very pleasant way. Our correspondent, if he wish to address his brethren, should do us the service of writing legibly, and them the compliment of writing elegantly, or at all events carefully.

Custos.—There is no medical orphan school; the greater is the pity. The Provincial Association alone has the funds for such an institution.

A Poor-law Guardian makes a very sorry defence for his parsimony. The "confiscation of property" is a selfish appeal of small force, where the first necessities and rights of the citizen are in question. The "Guardian" also omits his "name;" another instance of overstrained economy and caution.

The letter of "C." has been received.

Dr. McCormack's pamphlet shall have early consideration.

The article on "Quackery," through the "Journal," or the advantage of an hospital appointment, hardly requires insertion.

M. R. C. S. should address his complaint at the "dismal falling off in the 'Quarterlies'" to their publishers. The retirement of Dr. Forbes on one side, and the lamented death of Dr. James Johnson on the other, accounts for that "dreary waste of literature," without one "bright spot" to rest the eye or memory on, our correspondent complains of.

Letters and communications have been received from Dr. Aldis; Mr. M'Lean, Ballabea; Mr. Spencer, Hindon; Mr. Rossiter, Williton; Mr. Devereil, Dromore; Mr. Dale, Hlanley; Mr. Charlton, Birmingham; Mr. Jeffries, Ballymena; Dr. Goate, Ladbury; Mr. J. Vills, Crewkerne; Mr. Walker, Wakefield; Mr. Davies, Chester; Mr. Webb, Whitechurch; Mr. Morris, Banbury; Mr. Spurrell, Bexley; Mr. Lewis, Mountrath; A Poor-law Guardian; M. R. C. S.; Dr. McCormack; Custos; True O.; L. F. B.; Senex; S. J.; Philo, Dublin; A Country Surgeon; A Union Surgeon; M. D., Brixton; Mr. Norris, South Petherton; Mr. S. Seaton; T. B.; A Constant Reader.

POOR-LAW.—The numerous correspondents who have addressed us on this subject will pardon us if, from a regard to other interests, we have found space for comparatively so few. We have sought in our insertions to give samples of the different classes of writers.

THE MEDICAL TIMES.

SATURDAY, OCTOBER 2, 1847.

CONVENTION OF POOR-LAW DOCTORS.

WE are rejoiced to witness the public spirit shown on this subject. The union surgeons are truly up and doing. In the benevolent work before them there is but one mind and one heart among them. This is hopeful—cheering—excellent. But to business!—Thought—writing—earnestness—zeal—all is nought without that matter-of-fact quality—business!

All agreeing that there must be a Convention, the first want is an honorary secretary. Our voluminous correspondence on this subject has proved that there are few union surgeons who are so situated as to unite those advantages of leisure, residence, and peculiar qualities which would enable them to do efficient justice to this very troublesome and onerous office. In this difficulty we are happy to announce that T. Piers, Esq., barrister-at-law, 43, Connaught-square, has liberally undertaken to perform for

the profession, so long as it shall be felt desirable, this responsible and arduous duty. His legal knowledge and business habits fit him to render useful services to the *Convention*.

We propose that the *Convention* be held on Tuesday, October 12. The place of meeting to be at Charing-cross—a central point—near all the Government offices.

Mr. Healey has undertaken to make known the time and place, by circular, to every union surgeon.

He will be happy to receive in the mean time the names of gentlemen who propose to attend. He will also receive and acknowledge any subscriptions towards the expenses of the *Convention*.

THE FIRST OF OCTOBER.

"Hæc olim meminisse juvabit."

THERE are certain seasons of the year that are invested with particular importance in the estimation of particular classes of people. Married people, for instance, have a very natural regard for their wedding-day; and those to whom matrimony has proved a benefit and a blessing make a point of periodically illustrating the fact, by enlivening the said day with a hilarious plum-pudding, and certain tender sentimentalities having an embodiment in certain bumpers of wine. A similar good old custom prevails as an enunciation of the advent of every fresh birthday, amongst those respectable souls who are philanthropical enough to think their own lives, or those of other people, worth caring for, and the beginning thereof worth commemorating. Particularities like these have given rise to festivities and celebrations, in annual remembrance of things having a personal or a national importance. In fact, so many of the occurrences in this mundane sphere stand out in their own individual consequence, that there is not a day in the whole three hundred and sixty-five of our planet's gyration that is not marked as being a memento of something in which one person or another, or sundry such, are interested.

The 1st of October, now, is a day in which three very large, but very different, classes of persons, are affected by appertaining circumstances.

The gentleman, conventionally so called, easy in his income, and indifferent about the employment of his time, which, like a cumbrous thing, he tries to get rid of with as much pleasantry and as little exertion as possible—this said gentleman, the prototype of Solomon's lilies in all but their innocence and loveliness, hails the advent of the month of October as the season of wily slaughter, when with his dog and his gun he can chase a poor pheasant over hill and dale, and effect its sacrifice in his enthusiastic devotion to the duties of a sportsman. The more he kills, the merrier man he, when, with his companions in bloodshed, he carouses at night-fall over the bottle, and calculates how much of the harmless happy life of inferior creation has been lessened by his prowess of this day. Well! there may nothing really wrong in it, and we suppose there is not, or in a civilized, semi-sanctified country like this, the practice would find fewer patrons amongst those whose professional obligations speak of mercy and compassion, even towards the smallest of God's creatures.

For ourselves, however, we prefer to discourse with the man who can boast of the number of lives he has saved, instead of those he has sacri-

ficed. This man, and we proudly say there are many of his class, is the second of those whom we have alluded to as particularly interested in the 1st of October. His interest in it is only of reminiscence, but it is not the less sincere and hearty and affectionate because it refers to days that are gone by. Rather, like the friendship that twines itself round the memory of the dead, it clings the closer and the more tenderly as the lapse of time threatens to tear it from an embrace in which the best and warmest emotions of the soul are enwrapped!

The individual now before our mind's eye is the general practitioner of the day. There are many varieties and subdivisions of him, but we will take three of his phases in which to view him according to the purport of this article.

There's the patriarch of the profession, then, with his grey hairs and tottering gait, betokening lengthened years and lengthened servitude in a calling to whose members the honour of a prolonged life is a privilege rarely granted. The commencement of October re-views in his good old heart feelings that lack little of the freshness of that memorable time when they first visited him in the ardour and enthusiasm of his boyhood. He remembers how the spirit of solitude sat upon him as he grasped the last hand extended over his father's threshold to bid him a voiceless good-by, when he turned towards London—a student! He recalls the feelings that entranced him when he listened for the first time to the prelections of Hunter or Brookes, or the earlier discourses of Abernethy or Cooper. He thinks of the eagerness with which he drank knowledge from those fountains so celebrated for imparting it; and how gladly he availed himself of the various opportunities of becoming practically eminent in the quiet country place he had fixed upon for a residence. And then he speaks of the good that has come of these things in upwards of half a century's experience. He recounts, triumphantly, his difficulties and dangers and gains, and, in measuring these last, wonders how they will extend themselves, with advantage, over the long line of children and children's children that grace his home and make it happy! Nor is he forgetful, in gratitude, of the many occasions in which Providence has kindly placed in his way the opportunity of doing good. He has a store of little pleasantries in this wise with which to greet those who gather round him in company. The scenes of sorrow for the dying or the dead, in which his solitary voice has breathed a balm into the heart of the helpless mourner—the occasions of anger and inquietude, when his mild intervention has stayed the strife, and stood, angel-like, an interposer of threatened bloodshed—those he has relieved in their hunger, and those he has rescued from ruin, are happy items of lifetime, upon which it is at once his pleasure and his honour to dwell. These are the things that make grey hairs really venerable, and that extend to the authors of them a hope beyond the grave! May it be the privilege of future, as it has been of previous, generations of our profession to have those goodly truths told of them as leading traits of their history!

Then there is the practitioner in the height of his popularity—every hour of his time employed in the acquisition of fame or of fortune. Busy though he is, and bright as are his possessions and prospects, he can yet spare a leisure thought reflectively upon the time when he was only at the foot of the great eminence whose summit himself constitutes. To him the commencement

of October brings the remembrance of the time when, not out of his boyhood, he wondered whether he should ever be actually a man—when, starting as a student, he tried curiously to peer into future years, and see whether he should pass his examination, and become a practitioner, and have patients who would trust their lives in his hands—when, instead of being dependent upon the bounty of his father, he would be able to earn his livelihood, and have spare money of his own. These old thoughts, painful and anxious as their first visit was, are now called up as good jokes, the hobgoblins of youth, and the rich practitioner drains a glass to the memory of those cloudy days, when he little thought how bright a sun of prosperity was in store for him. Let these men, who have enough and to spare, remember in kindness those who are in the outset of a life whose beginning they themselves found difficult. The man who has toiled up the steepest parts of the hill of existence must have a poor heart if he cannot, when out of danger, lend a hand to those who are struggling in the midst of it.

We say thus much, to introduce our third friend in the list of practitioners. He is last on the said list, but the time may come when he will prove "the star of the goodly company." He has had his name on a shabby door, in a secluded street, just twelve months; and the 1st of October recalls to his mind the time when he went to London with a gay heart and good prospects, eager to carry off the honours of studentship, and make them tributary to his triumph as a practitioner. He was the best man of his day—took the highest prizes and honours, and stood alone in the achievements of his examination. But he had barely passed this, when his father's death left him penniless, and he began the world with its frown and ill favour in his face. A year has gone away, and he has made little head against these ungracious things. Patients are few; payments fewer; and debts numerous. Never mind, my fine fellow, your time has to come!

"Endure and shrink not; you of nobler clay
May temper it to bear—it is but for a day!"

The 1st of October reminds him of when he commenced his London studies, and of the cheerful prospects connected therewith; he thinks of these things, and contrasts them with his present difficulties, and wonders whether brighter days will follow. Yes, many that are much brighter! The booby that rolls in yonder carriage, who got into practice when good men were wanting, will one day tremble in his wealthy shoes when you meet him in consultation. There was only one chance open to him; there are many open to you, generous-hearted, accomplished boy: take your time, and you will take your treasure also!

So much for the past Octobers, and those concerned in them. We must now say a few words about the present, in which the last of the three great parties we mentioned are interested—the students. Those of them who have studied in bygone sessions, and those who are now commencing studentship, are alike subjects of interest and anxiety to us. Upon each forthcoming session we have willingly devoted special columns to their service, and we cheerfully continue the practice. Retrospects and prospects are often equally profitable; in the medical profession they are especially so, inasmuch as the experience of those who have toiled through the difficulties and have attained the honours of practice can be made to bear with frequent advantage upon the minds of such as are beginning

the hazardous career of physic. It is hazardous, however, only to the idle and the dissolute; the genuine student will ever find its most pleasant and profitable paths open to him. Let him, both early and late, betake himself to the duties which his choice of a profession imposes; let him pursue its difficulties with ardour and diligence; and successful studentship and a bright career of practice will assuredly await him. In a season like this, a word spoken admonitively is seldom without its advantages. There are many suggestions to offer, and many warnings to give, concerning the student's life, which we shall submit in due form in another article. In the meantime, we congratulate those who have commenced the session of 1847-8.

THE NECESSITY OF ORGANIZATION.

There are three epochs in the history of all those voluntary associations which survive to develop them. The first is that of enthusiasm, when popular feeling, rallying all its gigantic energies, rushes into the struggle against usurpation, violence, and wrong, with an undisciplined but dauntless devotion. The next is that of dismay and indifference; when cowed by defeat, passion subsides into apathy, and courage dwindles to despair. The third is a renewal of spirit, of hope, and of strength; the heart recovers confidence, the energies react, and the resolution to obtain redress and to establish the cause of truth revives with a subdued but a more enduring and irresistible vigour; the character of permanence is impressed on the organization, its opinions are authoritative, its progress steady and sure. We trust that the National Institute has arrived at the last epoch.

Very few associated bodies survive the second stage to which we have referred. The apathy of the public is communicated to the official authorities; doubt paralyzes action; new objects entice, and the old love is abandoned to make way for the new. Unless, also, the leaders of such associations are deserving of confidence and respect, it is quite impossible, after the first defeat, that they can ever regain their influence. At the onset of every great movement, little men may attain high positions; the public do not stop to investigate characters or claims: their cause fills their minds, and they care nothing who may be the instruments, provided that the end be achieved. Defeat, however, instils circumspection, individual claims are scrutinized, and in proportion as these are affected by the examination is the chance of maintaining the integrity of the associated body. It is scarcely necessary to apply these remarks to the history of medico-political associations. How many of them have we not witnessed careering valiantly before the gusts of popular enthusiasm, and, when the atmosphere has calmed—

"Go down at sea,
When heaven was all tranquillity?"

A leaky hull, a bad pilot, a sunken reef—one or all—have stranded the fated vessel.

The National Institute has escaped these insidious dangers, and the wreckers who were anxiously watching her from the coast, gloating over her anticipated destruction, and counting their spoil, are now retiring with visible chagrin and uttering impotent sarcasms at her speed and trim.

Our friend the Coroner cannot retire from the beach without stopping to cast many a wistful lingering look at the prize that has escaped his violence and his rapacity. What a booty would

he not have had if the ship had struck! What good characters would he not have plundered—that a number of excellent motives would he not have chained to ignominy—and what honourable feelings and high hopes would he not have scattered and belied! Disappointed man! He cannot help sympathizing with his misfortunes, despite his malevolence and his vicious practices! The poor fellow is almost raving with vexation:—he foams at the mouth, stammers, shrieks;—ever and anon, in his moments of ecstasy the words, "National Institute," "Apothecaries' Society," escape incoherently from his lips; he clinches his hands, fights with shadows, and, like Molière's Miser, strikes his own arm, and cries out that he has at last caught the thief!

Thomas Wakley has declared at various times that the National Institute and the Apothecaries' Society have been duly joined together in holy matrimony, and he seems to think that what he has joined together no man shall dare to put asunder;—nay, he even denies this right to the interested parties; and, notwithstanding the recently published resolutions of the National Institute, protests that they are still inviolably united, and that his fiat is necessary to a dissolution of the bond. The National Institute remonstrates with the Society of Apothecaries—Mr. Wakley deprecates its resentment—he is ridiculed for his pains. Blessed are the peace-makers!

It would be mere waste of words to dilate further upon the amiable benevolence and gracious solicitude which the Coroner displays upon all available occasions for the success of the labours of the National Institute. We are much obliged to him, on the part of the general practitioners, for his disinterested kindness, and for those gentle sympathies which so enviably distinguish him, and which he is always so prompt to exhibit in the cause of independence and truth. The tender spontaneities of his heart are exceedingly affecting.

It is clear, however, that, without his assistance, and in despite of it, the cause is advancing, and will triumph. There is an awakening to their great interests throughout the profession. They are beginning to feel the strength and the ardour of combination. The union surgeons are rising to a sense of their wrongs; they have long been trampled upon by ignorant and arbitrary poor-law guardians; their injuries have found a voice, and they are resolved no longer to be the helots of a mercenary plebeian despotism which recognises neither the rights of suffering humanity nor the proprieties of gentlemanlike demeanour.

The National Institute declares itself prepared to aid the labours of those gentlemen who have stepped out to defend the cause of their injured brethren, and we hope that this assistance will be as useful as we know it to be zealous. The union surgeons may now begin their crusade under flattering auspices; and if they should now neglect to combine, and to insist upon redress, they can blame themselves alone. Mere talk never yet carried a cause; action—action is the great political engine to break down abuses or to impress new principles upon the institutions of the age.

The profession are usually too ignorant of the discipline and tactics of a popular agitation; and they are also too reserved, too obstinately dignified, to employ the proper means, when they happen to know them, to compass a large success. Their duties are antagonistic to public

commotion; these lead them rather to the quiet chamber of death than to the noisy and tumultuous arena of political strife. Their habits are detrimental to public warfare; personal animosity, a vague dread of public opinion, unacquaintance with the arts and practice of the meetings, all conspire to render their efforts in the cause of justice inefficient and abortive. Let them know, however, that there is no mystery in public business: very indifferent people make very good public men; all that is required to enable a man to do his duty in that capacity is the resolution to do it. We hope that hundreds of union surgeons will come to this resolution.

NORWICH HOSPITAL DOMESTIC ECONOMY—WATER AND WASHERWOMEN WANTED.

CHARITABLE institutions are places which, we are taught to believe, are not only founded and supported by persons of high moral character, but who also take so much interest in their prosperity as to use the most efficient vigilance to prevent the existence of abuses amongst them. Founded, as these places are, ostensibly for the promotion of the best objects, and managed by the best men, to call in question the efficiency of the one or the integrity of the other requires no small amount of moral courage. The reformers of charitable abuses have not only difficulties to encounter in bringing before the broad light of day the imperfections which they discover, but in making that impression on the public mind which is absolutely necessary to accomplish beneficial results. No class of persons know better how to shield abuses than the benevolent managers of eleemosynary institutions; and, when compelled to stand upon their defence, none use more dangerous weapons against an adversary. He must, in the first instance, look well to himself, for, though at the onset he may have made the attack, he will speedily find that for a season, at least, he must act on the defensive. His character will be assailed—his motives impugned—his conduct denounced—while the divine armour of the governors, as impregnable as the far-famed shield of Achilles, bids defiance to the keenest shafts. We should be led to suppose, if permitted to draw conclusions from what has already occurred, that all things attached to religious or charitable institutions—be they good, bad, or indifferent—are "tabooed," and to lay hands upon any one of them is a sacrilege punishable without benefit of clergy. Yet, in spite of danger, there have been individuals with enough courage and philanthropy to attempt the removal of that which disfigures charity and curtails its usefulness.

Such champions have been found on behalf of the Norwich Hospital in the persons of Messrs. Dalrymple, who, having discovered certain abuses in that establishment, considered it their duty to make them known to the public. This was just what it was their duty to do, though there has been an attempt by some parties to call in question the propriety of such a proceeding. It would have been an act of supreme folly, after having ascertained how much the hospital needed reformation, to have left the work to those under whose eyes gross mismanagement had occurred. Doubtless there would have been got up some select meetings, many commonplace speeches, and more good promises; while the persons for whose benefit the hospital was especially erected would have derived as much benefit from them as the world does at the present time.

from the efforts of philosophers to find out perpetual motion.

The facts, however, are out, and they are certainly of a very astounding nature. "The comparison," it is said, "of other provincial hospitals with Norwich, first opened our eyes to the enormous disparity between their cost. We found that Norwich was more costly, that it admitted fewer patients, and cured fewer per cent. than any of its size; that, in fact, compared with others, its utility was in an inverse ratio to its cost." In order to establish the truth of these assertions, there is a comparison made with the hospitals at Bedford, having 727 patients admitted yearly; Cambridge, 742 Derby, 741; Hull, 745; Leicester, 776; Northampton, 882; Nottingham, 1128; Oxford, 922; and Worcester, 971, with those of Norwich, having only 607 patients. We have not here space to give the summary, but from it we learn that at Norwich the cost of maintenance per head is 120 per cent. dearer than at Hull, and 4½d. per day more than at Derby; the cost of drugs is 4s. 8½d. more than at Nottingham, and the patients remain 24½ days longer. There are 302 patients fewer cured than at Leicester; the cost of washing is 220 per cent. more than at Derby; the cost of nursing is 322 per cent. more than at Hull; while the quantity of meat allowed per week to each patient is 2lb. less, and that of bread 1lb. 6oz. less, than at Leicester; and the quantity of beer 5½ pints less than at Oxford.

It appears also that the charges for night-nurses in the matron's account amounts to £93 in each of the years 1845 and 1846, for 1917 nights in the one year, and 1869 in the other; the total number of accidents and operations having been 160 and 178 in each year respectively. The whole number is equal to 36 and 37 nights' nursing per week. "We do not pretend," it is remarked, "to say how it is; but other hospitals, whose proportion of cures far exceed Norwich, manage to attend to a much larger number of patients in a week with 21 night-nurses, than Norwich does with 37; and, next to professional skill, on nothing does cure more depend than nursing." After referring to the diet of the house, in which they say that there is a difference of above 400 stone of meat and 200 stone of bread, between the estimated and actual consumption of 1845, and of 80 stone of bread and 300 stone of meat in 1846, they mention the following defects in the establishment:—1. No efficient system of checks, so that it is not known the nurse does not say a patient is to have full diet, when middle or low is ordered. 2. No means of ascertaining that the quantities of food sent in by the tradesmen correspond with what the patients and the establishment do and ought to consume. 3. No check on wine, spirits, porter, or beer; so that these articles may be drawn by the nurse out of stock long after the patient has ceased to have any of them. 4. No taking stock. The cook and all the night-nurses sleep out of the house, so that there is an easy mode of conveying anything out of the house. The perquisites at the hospital must, under these circumstances, be very good; and for the parties just mentioned there must be good fat livings, and we doubt not but the "inner man" or, rather, woman is abundantly nourished thereby. Doubtless these parties think the management of the hospital bordering on perfection, and, if called upon to give evidence, would exhibit it in such fair colours as to win the approbation of all other establishments of a similar kind. We

cannot wonder that so many nurses are wanted for pregnant as they must be with beef, mutton, and beer, they must be soon wearied and require help. John Hunter used to say that bad surgeons were like bad carpenters—they made work for one another; the sentiment, we suppose, would hold good if we apply it to nurses—the Norwich Hospital itself being witness.

But, while the female functionaries are taking care of themselves, they do not manifest much regard for the external comforts or cleanliness of their patients. Messrs. Dalrymple tell us—"It has been complained, and it can be proved, that one towel only is allowed per ward per week, so that persons otherwise afflicted, but whose skins are wholesome and clean, have to wipe on the same cloth with those whose skins are diseased and loathsome. That soap is not to be had in some of the wards, though allowed as a matter of course from the stores of the hospital, while articles are sold and made a source of perquisite by the nurses in the wards." It appears that at one time there was a man in the hospital covered from head to foot with some cutaneous eruption—"as bad a case as ever was admitted;" and yet the other patients with clean skins, viz., free from disease, were obliged to use the same rags to wipe their flesh as their leprous companion. Such an occurrence would be disgraceful to any institution, much more so in one established for the express purpose of restoring health to those who, in addition to poverty, are afflicted with disease. Notwithstanding all the efforts of the house-visitors, who made a report, this part of the statement of Messrs. Dalrymple could not be got rid of, and a lady, whose servant had been in the hospital, had complained to the Rev. D. Mathias, that the patient had been compelled to use the same towel as those whose skins were diseased; and on inquiring of the matron he found the statement was correct.

These statements having been made public, as a natural consequence the managers of the hospital met together in order to investigate them; and it has been resolved that for the future there should be more towels, soap, and water furnished to each ward; and that, for the hot baths especially, the number of articles for the drying of the body should be increased. We congratulate the patients with healthy skins upon this important move, and we hope that the good work on their behalf which has thus been so well begun will be rendered complete by the addition to the establishment of a fresh number of washerwomen and a good supply of soap and water.

It is a matter of regret when charitable institutions are found to be inefficiently managed; and, while it is an ungracious task to expose the faults of those who hold offices of public trust, it is, nevertheless, oftentimes an imperative duty. We sincerely hope that the governors and other official persons connected with the Norwich Hospital will henceforth look more to their servants, that they efficiently perform their duties, and that the sick poor under their management may have all that attention which such an establishment professes to afford.

MR. MAYBURY AND CORONER PAYNE.

THE droll gentleman—who was supposed by competent authority to have perished under the influence of temporary insanity about the period of the City election—has been lately showing that the effect, at least, was not so total as was fancied,

by a long letter to a sympathizing contemporary Mr. Payne, being very systematic in his logic, can only respond to the accusations made against him in our columns by letters to contemporaries! The same ideas of the fitness of things which offered this infinitesimal dose of public humanity as the opponent of the Prime Minister and Baron Rothschild—and to the first constituency in the empire!—pervade his exculpatory correspondence. Charged with some folly at the assizes, he is just the man to go to a judge-and-jury club to deliver his defence!

Now, how did Mr. Maybury, who stood on excellent terms with Mr. Payne till—as a City voter—he was unable to recognise the coroner's singular merits as a parliamentary candidate, first find out how much he had lost in coronatorial estimation and influence, by his unfortunate lack of political discrimination? In this way: Summoned by the coroner's authority, Mr. Maybury bore all the inconveniences of personal attendance at the time and place fixed. Mr. Maybury had visited the deceased on the first discovery of the suicide. He had been summoned by the coroner's warrant and attended. Coroner Payne, however, contrived to do without his testimony, and Mr. Maybury, therefore, must contrive to do without the fee! This is Mr. Payne's logic! or, as Shakspeare has it, "crown's quest law" in the city of London.

Mr. Maybury has sent us his remarks on the defence of Mr. Payne, whom he accuses, with some evidence, of mis-statement, calumny, and misrepresentation. It is wholly needless to publish the statement. There can be little doubt that Mr. Maybury was not told before the inquest that his attendance was unnecessary; and there is none that he behaved there as a professional man should; or that, being summoned by the coroner, he is entitled, in reason as well as in law, to the statutory fee. Mr. Maybury assures us that he will in a day or two test the point; and, when he does, Mr. Payne—there can be no doubt of it—will receive a very useful lesson, both in law and equity.

CONVENTION OF POOR-LAW SURGEONS

[To the Editor of the Medical Times.]

SIR,—Will you allow me a portion of your valuable space for a few observations on the above subject, and in particular with reference to the letter of "C.," given in your leader of Saturday last? The remarks contained in that letter are pointed and forcible, and I fear calculated to deprive the poor-law medical officers, to some extent, of the support of the other portion of the profession; and I am sure you will excuse me, if I think that your space did not allow of your dealing so much destruction to the fallacies of our friend "C.," as those fallacies deserve. "C." sets out by throwing all the blame on the profession for the present preposterously unmunerative salaries of those officers. In this I believe that "C." is partly, but not entirely, correct. There cannot be the slightest doubt that the *Times* correspondent, "S. G. O.," has truly represented that the ultimatum of a large number of poor-law guardians is, regardless of consequences to the poor, to "keep down the rates"; but, before we condemn the local boards unsparingly, we should remember that there is to be found among them a section of gentlemen who, feeling to the fullest extent the evils complained of, and striving to emancipate their medical officers, are yet met by the argument that, if even every medical officer were to resign, plenty others would be glad to fill their places. I could mention a parish, Sir, where such high-minded guardians are to be found—(and the pro-

profession must one day have an opportunity of doing them honour)—gentlemen who have for years been in advance of even the medical officers themselves on this subject. I must, however, express my regret—and it is a painful fact—that there should be found in the ranks of the opposing parties gentlemen who, though poor-law guardians, yet belong to our own profession. Thus those to whom their medical officers might with reason look for support to the rational claims of those officers prove to be the greatest obstacles. Now, I take it that your correspondent "C." (and I would chide him with tenderness) would join them in their untoward dispositions and feelings towards their professional brethren. It is to the profession, to a great extent, that the blame is due, but it is to the whole mass of the profession—it is not to individuals. Let "C." ask himself what is the position of those to whom he attributes all the odium? It is not even the whole body of poor-law medical officers, for they have done nothing which the profession in general have declared to be dishonourable; and they have never yet been able to act in concert. Is it the individual who has singly taken office, when that office was essential (as I think by no means improbable in some cases) to his daily bread, or to assist in relieving his family from privations? Is it the newly-made medical man, who is naturally impatient for something whereon to exercise his newly-acquired powers, even were it but to banish the *curius* which must frequently arise from the sudden cessation of those anxieties and arduous efforts which, before passing his examinations, left him no leisure to think of anything besides? Or he to whom thirty guineas a year may be the only thirty guineas he may be able, at an early period of his strictly professional life, to get? The answer must be, that it is not to those that the odium belongs; for, as individuals, they are rendered by circumstances perfectly powerless. It follows, then, that it is the business of the whole profession. The interest of the subject does not belong to the present officers only, nor the present time only. It is also prospective; and I think there are few who will not agree with me, that the whole profession have an important stake in it. For we may rest assured, that without confining ourselves to individuals and the present, the degradation of such a large body of duly-qualified and, in very many instances, able and scientific gentlemen cannot but depreciate our profession in the eyes of the public.

Let the poor-law medical officers, then, at once take steps and unite; it is their interest directly; let the whole profession be earnestly requested to second and assist, for it is their interest at least indirectly. In the suggestions of Mr. Livett, of Somerset, I perfectly coincide. Let a memorial be agreed upon; and a deputation wait on the Home Secretary, and also on the Poor-law Commissioners. Let local boards be simultaneously memorialized. Let the thing be begun by some few zealous members of stability in London, and let all the poor-law medical officers in England and Wales be invited to attend; and let each one enclose a half-guinea to pay for the expenses of preparation; and I think there will be found many of us at our posts.

Apologizing, Sir, for taking up your valuable space, I must still beg to tender you my personal and best thanks for your able advocacy of the interests of the profession generally, and for your exertions in this matter in particular; and I beg to remain, Sir, yours, &c.,

WILLIAM HINDS, M.D.,
Poor-law Medical Officer.

[To the Editor of the Medical Times.]

Sir,—From your *Times* of the 25th inst., which I received this morning, I perceive that there is in contemplation a "Meeting of Poor-law Union Surgeons." Permit me, Sir, being one of the unfortunate, to say that I will be glad to join it and render it any assistance in my power in this locality. The remuneration of medical officers is a subject upon which I have of late written several letters. And coinciding

with your correspondent (Mr. H. W. Livett), that statements inserted on this topic in medical journals only are seldom perused unless by our equally unfortunate brethren (the public generally, whom it is of importance to enlighten on this subject, remaining in ignorance), I was fortunate enough to procure—through the kindness of the editor—their insertion in *Douglas Jerrold's Newspaper*.

I presume that if your correspondent "C." would peruse my letter therein, dated 18th inst., signed "Medical Officer," it might tend to enlighten him on the subject which he derides. I think that the medical profession owe a debt of gratitude to Douglas Jerrold for the powerful manner in which of late he has advocated their just claims upon the public.

I am, Sir, your obedient servant,
HUGH HASTINGS, a Poor-law Officer.

Stokenchurch, Sept. 29.

* * We are happy to bear testimony to the good feeling which—equally to the high talent of the editor—can we say more for it?—has been weekly displayed in favour of the medical profession through the pages of *Douglas Jerrold's Newspaper*. We are all indebted for such efficient advocacy of the interests of science.—Ed.

[To the Editor of the Medical Times.]

Sir,—I perfectly agree with your correspondent, Mr. Livett, in everything he says, except the following:—"I think the remuneration regulated by the number of cases and their distance, and paying us per case, would be equitable and satisfactory." Now, I think nothing could be more unsatisfactory and unjust, alike to the poor and doctor. By such an arrangement, the pauper and doctor would be at the mercy of the relieving officer; and if the medical order involved a certain expense of but a few shillings, it would be obtained with great difficulty, and then only in extreme cases, and after disease had taken such fast hold of the patient that many lives would be sacrificed. As an illustration: I attended a parish for many years at £6 per annum, and had plenty of work for the money. However, the vestry agreed to discontinue the yearly salary, saying they would give orders when necessary. The consequence was, that, for four years, they never gave an order or paid one shilling for attendance on their paupers, and this with a poor population of 500. It is true this was under the old law; but such has been, and will be, the result under the new. For instance: I made an application to the guardians of a union that I attend for increase of salary, and named the number of cases I had attended during a year (viz., 150 cases; salary, £25; population, 5000). They refused my application. I then threatened to apply to the commissioners, since which (one year) I have only had forty cases. And again, every union surgeon knows the difficulty in getting an order for what are called extra cases; indeed, so very cautious are some relieving officers, that I have heard of some who, when they give a medical order to a woman with child, add a note—"Not to attend in labour." For these reasons I fully agree with your correspondents, Mr. Livett and Mr. Cantrell, that a fixed salary, based on the population's extent and poverty of a district, and to include all cases, will be the most just and best, both for the paupers, doctors, and rate-payers.

But this subject will, no doubt, be fully discussed at the meeting of poor-law doctors, which, I trust, will be well attended; for, if we do not now bestir ourselves, we deserve to suffer all the insults and injustice we have hitherto undergone.

I am, &c.,

ONE WHO HAS BEEN A PARISH AND
UNION SURGEON FOR TWENTY-FIVE
YEARS.

Sept. 25.

[To the Editor of the Medical Times.]

Sir,—It is with feelings of no common character that I see the dormant energies of an injured race of men aroused into action to throw off the

incubus which has so long lain like an Atlas upon the individual welfare of the poor-law surgeon. The weight of intelligence which is about to bear on those who have the remedy in their hands, and the undeniable existence of the legal iniquity, are of themselves sufficient to guarantee a shortness and want of severity to the struggle which might not otherwise have been the case in those days of inaptitude to medical legislation. That a modification of medical remuneration is in contemplation at present cannot be doubted; and that it will be a niggardly one may be reckoned on with as much certainty: the various enactments emanating from Somerset-house, and others which have been disengaged in a more liberal atmosphere, and taking effect in the sister island, sufficiently prove that this will be the case. This, however, with the proper interference of the interested portion of the medical profession, supported by the rest who may not apparently be so, but who are, can not and will not take place. It is known to legislators that medical men are the most enlightened, liberal, and have the most correct notions of social improvement of any class of men of the present time. They likewise know that the influence for good which they possess is exerted and extends over every part of the British dominions. How can it be thought, then, that any government can be indifferent to the demands of such men? They cannot, and they are not. The blame lies with the profession itself: it will not allow them. That great destruction of strength, disunion, has ever prevailed amongst us, and shorn the hair of our energies for any improvement in our social and political status.

The present position of the medical connection with Somerset-house is lamentably debasing. Independence of thought and freedom of action, the natural qualities of enlightened understandings, cannot exist, much less be exercised, when allowed to be controlled by the hands of those who have never had their intellects impressed with the noble claims of our science. They have ever shown that their only object is to have the greatest good done at the least price. Instances might be brought forward where this maxim has been objected to by the medical man interested, but not in a way to have any effect on the iniquity which exists in every place, extensive as the law itself. They number by scores and hundreds who have had their indignation raised to its highest pitch, by the ungenerous imputations of ignorant guardians to their acts of self-denial and consecration for the poor under their charge; yes, and such we are content to pocket—a proof that we have some claim to the honourable designation of medical paupers as well as medical gentlemen.

"Organize, organize, organize," was the exciting cry of the late Dr. Chalmers, when concerned in the accomplishing of a great purpose; organization took place accordingly, and the accomplishment of the purpose was the result. The same should be the war-cry of medical men holding situations under the Poor-law Act now; and as sure as our organization is complete with our intentions be carried into effect. The shoulders of every one must be put to the wheel, and as certain as it is done the wheel will move.

I see you have occupied the pages of the *Medical Times* of late with the personal grievances of union doctors: this I think unnecessary; following out the tale of one is the tale of the whole. I may be allowed just to mention, that I have the exceedingly-large allowance of two shillings per case, and have to perform the operation of vaccination for the very liberal fee of ninepence. We must surely, Sir, be as "valiant as the wrathful dove, or most magnanimous mouse," to sit quietly under such disgraceful meetings.

To conclude: I hope you will continue your strenuous and able advocacy of the rights of union surgeons. Your paper is now the acknowledged organ of the profession—raised to this eminence by your talent, liberality, and zealous endeavours in the promulgation of scientific knowledge amongst its members. The country

THE MEDICAL TIMES.

surgeons are ripe for the contest. It is only for those in and about the metropolis to be stirring themselves, and making arrangements for the proposed meeting. "The time is most favourable, and not a minute should be lost."

I am yours obediently,
Haworth, Sept. 23. A POOR-LAW SURGEON.

[To the Editor of the Medical Times.]

SIR,—In the last number of your valuable periodical there are two letters from Union Surgeons on the subject of their grievances, and the wrongs which they endure, in common with other members of the profession who have been unfortunate enough to enter into a contract with board of guardians of poor-law unions to attend the poor and supply them with medicines on terms most ruinous to those who undertake such a task.

The question which naturally presents itself is, How can any man in his senses be guilty of such folly as to undertake these ruinous sacrifices? Can any one be so ignorant of human nature as not to know that the public invariably despises whatever they do not pay well for; and that boards of guardians, being no exception to the general observation, will almost certainly depreciate the services of individuals who seem to rate them at so mean a value? What opinion must the public have of men who seem so lost to a sense of what is due to their profession and to their own character, as to degrade themselves by accepting contracts made in the spirit of dishonesty by guardians, and meanly entered into by members of the profession? And yet we hear of great complaints made by these very men of ungentlemanly manner in which they have been treated, probably by the College of Surgeons; that they are not eligible for the council, &c. &c. These men, indeed, eligible for the council! numbers of whom are rushing eagerly every year in the spirit of competition to try for situations like these, which must irretrievably damage both the aspirant and the profession. The terms generally offered are such that the meanest tradesman would spurn at them.

But it is asked, why do not the Colleges of Physicians and Surgeons, along with the Society of Apothecaries, unite to make a strong representation to the Government of the injustice and ill treatment with which members of their body are treated in their laborious exertions in attending the sick poor? There are two answers to this question: the first is, that the spirit of jealousy between these respectable corporate bodies is so great that they will not act together; the next is, that, if possible, a greater feeling of rivalry and competition exists among individual members of the profession, who are too glad generally to do one another harm, by offering their services for nothing. The sure consequence of this is the degradation of the profession. Can any man be insane enough to imagine, that as long as boards of guardians positively have the choice of candidates who in some cases offer to supply advice and medicine to the poor gratis, even if the colleges were to stir in the business, their representations would be heeded? As long as men can be got who are willing to ruin themselves, it would be contrary to the doctrine of free trade to interfere.

Before concluding, the profession generally seems to require a little advice, and that is to be guided a good deal by the example of the lawyers, who never quarrel among themselves, but unite in protecting one another.

The medical profession might, if they chose, dictate terms to the public, who profit by their dissensions. If the profession were properly organized, and so united that no member would dare to do a degrading action, or act unprofessionally, which is punished in the law by being sent to Coventry by every one, so that defaulers are invariably ruined by none holding any intercourse with them, self-interest would then combine to uphold the suggestions of principle and the honour of medical men.

I remain, &c. &c.,
London, Sept. 23. A CONSTANT READER.

[To the Editor of the Medical Times.]

SIR,—There never was a time when medical men were so imperatively called upon to come forth from their privacy as the present. It is no fair that the battle should be left to the few; it is the business of all, both those who are connected with unions and those who are not. Never before was there such a general movement in the right direction. The Provincial Association, numbering its thousands, has taken up the cause of the oppressed union surgeons, and appointed a deputation to wait on Sir George Grey, to represent their case. It may be said that a congress of poor-law doctors is not called for till the result of the above deputation is known. On the contrary, I say it is more needful that the opinions of all may be collected, discussed, and some fixed principle agreed upon, and communicated to that deputation for their guidance at the interview. The National Institute, also numbering its thousands, has taken up the subject of medical remuneration, as well as that of quackery; and every general practitioner ought at once to enrol himself a member, and then we shall get a charter which will give us (what we have not at present) a standing and a home; for the College of Surgeons has degraded us, and the Apothecaries' Company will not defend us. Let us, therefore, have an *alma mater* of our own. I am ready with my subscription and services to promote so good a movement.

I am, Sir, your obedient servant,
Sept. 27. A UNION SURGEON.

HEMORRHAGE FROM THE UMBILICAL CORD.

[To the Editor of the Medical Times.]

SIR,—In the number of the *Medical Times* for September 11 there is an account of a case of hemorrhage from the umbilicus of an infant, arrested by ligature of the "tubercle;" and there is also a reference to another case published at p. 116 of vol. 16, which was fatal, and afforded an opportunity of ascertaining the source of the hemorrhage, which proved to be from the right umbilical artery. In No. 409 of the *Medical Times* there is also a fatal case of hemorrhage from the navel, and a notice of a paper or communication of Dr. Simpson, of Edinburgh, respecting the treatment, but not the pathology of the excrescences that occasionally spring up after the separation of the umbilical cord. Now, it appears to me that there is, probably, a connection between these two morbid states (that of a patent and unobliterated umbilical artery, and that of an umbilical excrescence), as both may originate from the same cause, viz., an excess of vitality in the vessels of the cord, that prevents its complete desiccation and the formation of a level cicatrix after its separation, by keeping up the circulation in the arteries, and consequently that of the capillaries of the cord, to some distance beyond the ordinary level of the umbilical cicatrix. So that, when the dried portion separates, it either leaves a raw, conical, vascular prominence, instead of a puckered surface covered by a moist new integument, or it exposes the open ends of the vessels, and thus gives rise to violent and dangerous hemorrhage.

M. Billard ("Maladies des Enfants nouveaux nés") has most accurately described the process of the separation of the cord, pointing out that it begins from the edges and extends to the centre, much in the same way that the stalks of gourds separate from the fruit, and that the desiccation of the cord is the chief cause of the obliteration of the vessels, as this latter does not occur until the completion of the former; also, he mentions that the projecting closed extremities of the vessels often form a fungous excrescence requiring the application of caustic for its removal; but he omits entirely the consideration of hemorrhage at the time of the separation of the cord.

If, therefore, we admit, with M. Billard, that the drying up of the cord is the cause of the arrest of the circulation in the arteries, it will happen that in very thick cords the vessels will

be still permeable after the cicatrix has begun to form round the base of the cord, and there will be a permanence of vitality in the vasa vasorum to a little distance around and beyond the closed extremities of the vessels; and hence the cicatrization of this portion will not be completed as soon as that of the surrounding surface of the navel, but it will form a conical projection or "tubercle," covering the cul-de-sac of the vessels, which, if separated by accident or absorption too soon from the dried portion, may become a source of hemorrhage; or, after the separation of the cord, if it be irritated by its friction against the walls of the cuplike hollow of the navel, by this time retracted, or against the clothes, it will be kept in a raw state, and will throw out vascular, warty excrescences very difficult to remove.

Such, in the cases I have witnessed, has appeared to me to be the origin of these tumours; and, though I have not had an opportunity of confirming this idea by a dissection of the state of the umbilical arteries after death, yet, if we grant that the arteries remain permeable as long as M. Billard asserts they do, the danger of hemorrhage and the existence of the excrescence would seem to be closely connected. In both the instances of hemorrhage cited, the separation of the cord occurred after the sixth day, which indicates a thick cord—the condition most favourable, according to M. Billard, for the occurrence of such accidents—which also was the case in the instances of excrescences that I have observed.

With regard to the treatment, I cannot say that I have been as successful as M. Billard and Dr. Simpson in the use of astringents, and argenti nitras, having, as frequently as not, been compelled to apply a ligature after the other remedies have failed, as was also the case in the instance mentioned by Dr. Simpson. The instances, therefore, in your journal of the successful application of the ligature appear to me highly useful, as showing that this mode of treatment is admissible for the removal of excrescences and the arrest of hemorrhage at a very early period after birth, instead of our being obliged to wait the effect of other means, often pursued for many days in vain, before we venture to apply a ligature (and only a very fine one would be suitable), lest it should accidentally enter through the tender tissues, and thus produce a hemorrhage from the unobliterated vessels.

Should you deem these observations worthy a place in the columns of the *Medical Times*, you will oblige, Sir, your obedient servant,
T. OJIER WARD, M.D., Oxon.
9, Leonard-place, Kensington, Sept. 24.

MEDUSÆ AS IRRITANTS TO THE SKIN.

[To the Editor of the Medical Times.]

SIR,—Your very learned correspondent (Sept. 1) Dr. Wisely has discovered a mare's nest, viz., that medusæ possess the property of stinging when irritated; "a fact which seems new to the naturalists and medical practitioners" in the vicinity of Rosneath. He then goes on to state that "the poisonous property seems not to be confined to any particular part of the animal," &c. &c.

Had this sapient man studied, or even read, a little natural history, he would have known better, unless, poor man, he prefers his own opinions to those advanced by Cuvier, Spallanzani, Dictionnaire, &c. &c.

From the time of Aristotle down, they have been known to possess the singular property of being luminous to a great degree in darkness, and of producing a painful sensation similar to the sting of nettles, when any of them are touched; hence their name *Acalephe*—sea-nettles.

Dictionnaire, who experimented on himself with the *Cyanea carulea*, relates the effects of them in these terms:—"The pain is pretty nearly similar to that which is felt on touching a bunch

of nettles; but it is stronger, and endures for about half an hour. In the last moments reiterated stings are felt, but proportionally more faint. There appears a considerable redness on all the parts which have been touched, and swellings of the same colour, which have a white point in the centre. After the end of some days, when the pain is gone by, the heat of the bed will cause the blisters of the skin to reappear."

Spallanzani, who tasted the liquor that issued from a wound in a medusa, felt a burning on his tongue which lasted for more than a day; and a drop having by chance fallen upon his eye, the pain was still more intense. The species which possess the property of urtication in the living state, have it also when dead.

This effect is owing to a peculiar gelatinous humour which issues from the great tentacula, the muscular zone of the umbrella, and the stomachal cavity. Expressed into different liquids, as salt water, but particularly fresh warm water or milk, it communicates to them a phosphoric light.

Let your self-dubbed naturalist, for further information, consult "The British Cyclopædia of Natural History," edited by C. F. Partington, 3 vols., article *ACALEPHÆ*; or "Cuvier's Animal Kingdom," by Edward Griffith, vol. 12, *ACALEPHÆ*; and there he will see recorded the opinions of moderns. But, should his zeal for natural history lead him further, he can have the description given by Pliny IX., ch. 18; or that by Dioscorides II., ch. 36; or by Matthioli, in his "Commentaries," published at Venice 1568, p. 365. "Tocchi con le manifanno subito un prurito grandissimo, alquale segue subito rossore infammato."

Every seaman and boy in her Majesty's navy knows by experience what "seems new to the naturalists and medical practitioners" of Rose-hearty.

Yours ever and wisely,
AN OBSERVER, R.N.

CROWNER'S QUESTS IN CARLISLE, ANNO DOMINI 1847.

[To the Editor of the Medical Times.]

SIR,—Your readiness in giving publicity to abuses of all sorts bearing upon the well-being of our profession has encouraged me to send you this communication.

I have hurriedly sketched an account of two cases, both of them were infirmity patients—both came under jurisdiction of the coroner; and for conducting the *post-mortem* examinations of them without his sanction I have met his sore displeasure, and, in the bargain, been threatened with imprisonment, besides an appeal through the Carlisle and local newspapers for the interference of the governor of the infirmity.

I refrain at present from further comment; waiting the decision of the governor.

I am, Sir, your very obedient servant,
EVAN THOMAS, House-Surgeon to the
Sept. 17. Infirmity.

FRACTURE OF THE BASE OF THE SKULL. COMPRESSION OF THE BRAIN.

POST-MORTEM APPEARANCES.

In November last, a man, aged fifty, was admitted into the infirmity, under the care of Mr. Page, in the following condition:—Nearly insensible; bleeding from the right ear; considerable rigidity of the flexors of the upper extremity; the left pupil fully dilated, and insensible to the stimulus of light; breathing stertorously; perspiring profusely; the pulse scarcely perceptible; and the breathing short and frequent, performed mostly by the pectoral and *nuchal* muscles; and, in addition, a contused wound; skin deep over the right parietal eminence.

The case being hopeless, no remedial measures were adopted except feeding him with beef-teen, conveyed in a tube over the back of the tongue. A great difficulty was experienced in passing a catheter into the bladder on account of some obstruction about the triangular ligament, sup-

posed, at the time, to be a tight stricture. He died thirty-six hours after his admission.

Upon examination, the following appearances were observed:—Fracture of the parietal, temporal, and spheroid bones; a thick layer of coagulated blood flooring the base of the skull; and extensive extravasation into and upon the left anterior and middle lobes of the brain; a stricture, hardly admitting a probe, was found in the membranous portion of the urethra; the mucous membrane of the bladder was sacculated, and the walls of the organ about half an inch in thickness.

LACERATED WOUNDS OF THE NECK, &c., PRODUCED BY A BEAR.

POST-MORTEM APPEARANCES.

About ten days ago, a man, aged thirty-two, was admitted into the infirmity, under the care of Mr. Page, in the following condition:—Insensible, cold, and pulseless, from the loss of blood; the back of the head was scalped, and the bone laid bare. Three deep wounds were observed on the left side of the neck: the upper, about 1½ inch in circumference, going into the substance of the parotid gland, between the mastoid process and the neck of the lower jaw; the middle, a little below the angle of the jaw, in a line with the sterno-mastoid muscle; and below this, the largest of all, but on a place somewhat posteriorly. A probe passed into the last named wounds, grated upon detached portions of bone, supposed to be the transverse processes of the cervical vertebra; blood welled out of the wounds for some time. Besides these, there were numerous smaller wounds of the same character on the opposite side of the neck, trunk, and upper extremities. He rallied from the immediate effects of the shock, and died thirty-six hours after the accident; the symptoms preceding dissolution being sickness, vomiting, restlessness, and great difficulty in breathing and swallowing.

The following lesions were observed after death:—Extensive effusion of blood under the platysma; the sterno-mastoid so much lacerated as scarcely to be distinguished from the surrounding mass of blood; all the superficial cervical nerves more or less injured; the third, fourth, and fifth cervical, the phrenic and spinal accessory, nerves were divided; the posterior branches of the external carotid, and the ascending of the subclavian, were lacerated; the transverse processes of the fourth and fifth cervical vertebrae were torn asunder, wounding the vertebral artery; the sheath of the carotid and sympathetic nerve were free from injury.

* * We have read the reports of the inquests Mr. Thomas attended; and cannot but think that the coroner in receiving that surgeon's able evidence exhibited a personal unamiability that by no means becometh his office.

DYSENTERY.

[To the Editor of the Medical Times.]

SIR,—I felt much pleasure in reading Dr. Ayres' letter on dysentery, in your last number, inasmuch as it brought to my mind the method of treatment recommended by M. Pringle, Chevalier, who, in his work, "Observations sur les Maladies des Armées dans les Camps et dans les Garrisons," tome second, 1771, gives a full account of the causes, symptoms, treatment, and *post-mortem* appearances of dysentery. After dividing dysentery into three stages he proceeds to show that in some cases, where the patient is plethoric, he bleeds once, but he omits doing so if the patient is of a feeble temperament. He then gives an emetic of ant. p.s., and ipecacuanha, observing, that if the emetic operated also by stool the patient became better. The author then administers ipecacuanha, in doses of five grains at a time, repeating it two or three times in the hour, until the patient is well purged. In the course of his treatment he gives sulph. sodæ, rheum, opiate clysters; enjoining strict regard as to diet, &c.

In page 47 he states:—

"Les autres médecins de l'armée ont suivi à-peu-près cette méthode dans la dernière guerre, et le docteur Ifuck en particulier, qui, ayant toujours été employé dans l'Amérique septentrionale, ou aux Indes occidentales, a eu les occasions les plus favorables de voir la dysenterie sous toutes ses formes. Il m'a appris que malgré la différence des climats, lorsque la maladie était épidémique dans l'armée, elle paraissait par tout avec les mêmes symptômes (avec cette différence seulement, qu'elle était plus violente à proportion que la chaleur du pays était plus forte), et que lorsqu'elle pouvait guérir, la cure se faisoit par les mêmes remèdes." Here there is a quotation too long for your pages. In page 40 he quotes from "Gul. Pison Hist. Nat. et Med. Indis Occident." lib. II., cap. ix. Speaking of ipecacuanha he writes:—

"Cette racine est peut-être plus cathartique lorsqu'elle est fraîche, que lorsqu'on l'a conservée pendant long-temps et en decoction, ou en infusion qu'en substance. Nous pouvons pareillement observer que Pison recommande la seconde et la troisième decoction pour les malades faibles, comme étant moins cathartiques et plus astringentes. J'ajouterai seulement ici un des principaux passages de cet auteur, qui a rapport à l'usage de ce spécifique:—'Dehinc ad radicem ipecacuanhæ tanquam ad sacram anchoram confugiendum, qua nullum præstantius aut tutius, cum in hoc, tam in plerisque aliis, cum, vel sine sanguine, fluxibus compescendo, natura excogitavit remedium. Quippe præterquam quod tutò, et efficaciter tonacissimos quoque humores per ipsum alvum, sæpissime autem per vomitum ejiciat, et a parte affecta derivet, vim quoque astrictivam post se relinquit.' Illud verò hoc modo perficitur drachmæ dñe radicis ipecacuanhæ in ʒiv. liquoris appropriati coctæ, vel per noctem macerata, cujus infusum cum, vel sine, oxymellis ʒj. exhibetur. Postridie semel atque iterum pro re nata, secunda imo tertia ejus decoctio repetenda; tam quod regi debiliores eam facilius ferant, quam quod astrictiva ejus vis tunc magis efficax appareat."

Connected and associated as ipecacuanha and dysentery are in my mind, I could not omit the above quotation. I must conclude, as I fear trespassing on the valuable columns of your journal; recommending your numerous readers to peruse the work, which will well repay their trouble, as it contains the views of several eminent physicians respecting the treatment of the disease. I am, Sir, your obedient servant,

WM. EXAMSON, M.R.C.S.-and L.A.C., &c.
Turnham-green, Sept. 18.

JACK KETCH A MEDICAL MAN.

[To the Editor of the Medical Times.]

SIR,—In your last number but one, it is stated that the executioner at Nantes, and the same functionary at Bourges, claim to be considered as practitioners in surgery by virtue of their office. Now, this is as it should be, and the fact furnishes a valuable hint to our medical reformers.

How comes it that this relationship has been so long unrecognised? Perhaps it is one of those things which are so very obvious that they are overlooked.

If a culprit is sentenced by court martial to be tattooed, a duly-qualified surgeon is very properly ordered to apply the acupuncture; if he is to be whipped, the surgeon must superintend the operation, and inspect the changes of colour in the epidermis; and yet, by a strange and unaccountable inconsistency, the important operation of *surg. per coll.* is intrusted to the hands of uneducated empirics, who often perform it in a most bungling manner. This cannot be wondered at, for how should a man be able to apply the ligature in a scientific manner who knows nothing of the relative anatomy of the internal jugular? or how can he calculate the amount of *descensus* (angled, length of rope) necessary to rupture the odontoid ligaments, if he has never studied the laws of animal mechanics, or calculated the cohesive force of organic structures?

Do, pray Mr. Editor, agitate this question. Urge it strongly and repeatedly upon the Government, upon the profession, upon the public. If you use your powerful influence as you ought, considering the importance of the subject, who knows but that the next Jack Ketch that is appointed may be a medical man! This would indeed be a triumph—the first step to an alliance of medicine with the state, and a crowning climax to the dignified progress, our profession has been making of late towards a “legal and social status.”

There will be no difficulty, I conceive, about the question of salary, for judging by what is going on daily among us (witness your own columns *passim*), there are plenty of surgeons quite ready to enter into competition for the appointment, for the mere honour of the thing, and to find the rope into the bargain.

One suggestion occurs to me in conclusion, and that is, that as the operation of *quo, per coll.* is undeniably a capital one, and happily not among the “ordinary exigencies of surgical ministrations,” none should be eligible to the office of Jack Ketch but Fellows of the College of Surgeons. This limitation is but due to the “dignity of the said college.”

I am, Sir, with all respect,
your old correspondent,
ECHO VERITATIS.

Sept. 21.

THE PROFESSION AND THE LIFE INSURANCE COMPANIES.

[To the Editor of the Medical Times.]

SIR,—The frequent applications made by various insurance societies to our profession for gratuitous information demands its serious consideration. I have recently been requested by four different offices to furnish replies to a long string of queries in reference to the past and present state of my patients who have been desirous of effecting assurances on their lives.

The medical certificate is so important a safeguard to the insurers as to be considered a *sine qua non*. It is of importance only to the insurance society, and therefore ought to be purchased by the party requiring it. I have invariably declined giving any information in such cases without first receiving my fee. The plan I adopt is as follows, viz.: on receiving a request from any society for my report in reference to the health of the party wishing to assume his life, I respectfully acknowledge the receipt of such request, at the same time stating my readiness to comply with their request on being furnished with the sum of one guinea; but I make it a rule never to give such information gratuitously. If the office decline remitting any fee, I furnish my patient with the name of some society who remunerate medical men for any information required.

In furtherance of this view, can you favour your numerous readers with a list of the offices who pay for medical reports, so that we may be enabled to accomplish the end we desire by enabling our patients to effect their object without submitting to the exaction of paying for medical evidence, which is of no service to them, but is intended as a security to the opposite party?

I am, Sir, your obedient servant,

Sept. 18.

AMICUS.

ASSISTANT-SURGEONS OF THE NAVY.

[To the Editor of the Medical Times.]

SIR,—Insertion in your widely-circulated and influential journal, for the following exposure of the present very anomalous and truly degrading position of the class to which I belong will much oblige,

A. ASSISTANT-SURGEON, R.N.

Every assistant-surgeon, previous to entering the navy, must have obtained the diploma of surgeon, and many, in addition, are doctors of medicine. Another very strict examination must also be passed before Sir William Burnett, the talented Medical Director-General. When we

join the respective ships to which we may have been appointed, instead of being treated as professional men, we are compelled to mess and associate with a set of noisy, half-educated schoolboys—midshipmen, naval cadets, clerks, assistants, &c.

We are excluded from the wardroom mess, not being deemed suitable company for the naval lieutenants, the paymaster, marine lieutenants, the naval schoolmaster, &c., until we have had our manners refined by a residence of some eight or ten years in the pure moral atmosphere of the midshipmen's berth!!

The junior marine lieutenants nominally rank below us, and the naval schoolmaster is a non-commissioned officer; yet both are admitted to the wardroom mess, and are allowed cabins, servants, and all the other privileges that are so unjustly withheld from us. The engineers in all our steamers, until lately, were only warrant officers; now they are very deservedly made commissioned officers, and admitted to the wardroom mess. May I ask, are we inferior to them? Nay, more: the gunners, carpenters, and boat-swains; in every ship afloat, are allowed cabins, servants, and all the other comforts that are denied us; whilst we, who by birth, education, and profession, are gentlemen, are forced to sleep in hammocks, in an open steerage, among common sailors and marines, and to dress on the lid of our chest, the only article of furniture we are allowed to keep on board, and which must serve for toilet, wardrobe, library, &c. We are refused the smallest corner where we can retire to for study.

The natural consequence of this tyrannical treatment is, that we must close our books for ever, and give up all idea of deriving any further information from that source. We must, of course, retrograde in our profession, and of necessity forget much of that valuable knowledge acquired by years of patient study. Many of us fall into habits of professional indolence; whilst others, but the number I am happy to say is few, try to forget their wrongs in pursuits equally injurious to health and reputation.

Thus situated, we have no other resource than the sympathy of our professional brethren on shore. We call on them to petition the Legislature on our behalf to remove our degrading grievances, and to place us in that position we are entitled to, viz., a perfect equality with assistant-surgeons in the army, who all mess with the field-officers and captains of their respective regiments.

Portsmouth, Sept., 1847.

DEATH OF DR. CURRAN, OF DUBLIN.

We have heard with unaffected sorrow of this event. There were few physicians of higher promise. Already he has done much not unwelcomed by us and our readers; and he was engaged in undertakings of greater importance when death by fever closed his useful career. The following well-written notice we extract from *Saunders' News Letter* of Monday last:—

“Among the many instances of death which in the present state of our unhappy and afflicted country we are daily called on to record, we have not yet met one so untimely or so harrowing in its circumstances as that which it is now our painful duty to announce. Dr. John Oliver Curran, whose illness we mentioned with extreme regret some days ago, sunk rapidly during the latter part of Saturday, and through the night of that day; and, notwithstanding all that the skill and brotherly aid of the ablest men in the profession could effect, the fatal typhus claimed him for its victim, and he expired at nine o'clock yesterday morning—another bright name added to the list of martyrs of the medical profession in Ireland.

“Who this young man was we need not tell our readers. His private character—amiable, generous and humane—the best of sons, the most affectionate of brothers, the staunchest of friends

—we have not the heart to descant upon. Our grief is yet too fresh and gushing to permit us to detail in words the many virtues, the unselfish kindness of heart, the noble disregard of danger, and the thousand graces of social life which endeared him to his friends and to all that came within the benign and gentle influence which he invariably shed around him.

“His transcendent talents, his great professional acquirements, the rapid strides he was making in his noble career, the bright promise for the future, and the achievements of the past, are well known to his brethren—the best judges of his pursuits and labours. All these shall no doubt be embalmed in their fit and proper place by those capable of appreciating their merits; but to the memory of Dr. Curran we have, in common with all the well-wishers of our native land, that tribute to pay which does not require us to be either private friends or professional brethren.

“Let it be remembered by the Irish medical profession that he was the man who first raised his voice against the insult and indignity offered to that body, by refusing to accept the miserable stipend proposed as remuneration for risking their lives in defending the Irish peasant artisan from the ravages of the pestilence which now stalks amongst us. And yet, while he thus spurned the degrading offer, for the benefit of his brethren, he daily toiled without fee or reward, in the haunts of misery and distress, to relieve suffering, to succour the fever-stricken poor; and in his generous endeavour to rescue others he himself fell a sacrifice to the Moloch of pestilence and misrule.

“Let it never be forgotten by the Irish people that to the courageous disregard of official threat—to the honest and indignant appeal made in their behalf to the sympathies and benevolence of Europe by Dr. Curran—were the gates of fever-sheds, the barred portals of hospitals, and the stern hearts of rulers opened to afford them shelter and a cup of water when they blackened, exposed to the sun and sky, in the lanes and ditches around our metropolis.

genius, country, to science, and his friends. In John Oliver Curran his mourning family have lost the most feeling and affectionate of relatives; an aged father his only son; his friends, a soul of sterling and enduring worth, unalloyed by selfishness, unpurchasable from its allegiance; the Irish School of Medicine, the University, and the Royal Academy, one of their most promising sons. Science may mourn the most devoted of her votaries; Ireland a man whom she could never spare, now least of all; and humanity a friend. For our rising literature his able pen was wielded. For our dawning nationality his manly voice was raised. To elevate us in the scale of nations he not only toiled, but by his conduct and deportment (the real tests of patriotism) mainly contributed. No foreigner of distinction ever visited the Irish metropolis within the last few years without feeling indebted to Dr. Curran.

“Gentle and unobtrusive in his manner, a tone of serious thought and an extraordinary fund of information, with a remarkable facility and clearness of expression, graced his conversation, and rendered him one of the most delightful and instructive of companions. If being utterly devoid of envy towards others, and a holy, never-failing desire to do good, could ensure a man the world's friendship, then had Dr. Curran no enemies.

“His writings are eminently remarkable for their unbounded research, their power of argument, and perspicuity of style; no man understood better the force and value of the English language. Dr. Curran had but entered his twenty-seventh year. We understand his funeral will take place on to-morrow morning at seven o'clock. He was professor of the practice of medicine to the Apothecaries' Hall, a licentiate of the College of Physicians, a graduate of Trinity College, a member of the Royal Irish Academy, and attached to all the literary and scientific institutions of this city.”

GOSSIP OF THE WEEK.

WAR-OFFICE, Sept. 24.—72nd Foot: Assist. Surg. Edward William Gray, M.D., from 81st Foot, to be Surgeon, vice Dumbreck, promoted on the Staff.—Hospital Staff: Surg. David Dumbreck, M.D., from the 72nd Foot, to be Staff-Surgeon of the First Class, vice Denis Murray, who retires upon half-pay; John Henry Smith, M.D., to be Assistant-Surgeon to the Forces.—Sept. 28.—2nd Dragoon Guards: Assistant Surg. Alexander Smith, M.D., from the 93rd Foot, to be Assistant-Surgeon, vice Wheeler, appointed to the Staff.—33rd Foot: Staff-Surg. of the Second Class James Townsend Oswald Johnston, M.D., to be Surgeon, vice James Murray Drysdale, who retires upon half-pay.—73rd Foot: Assist.-Surg. Benjamin Swift, M.D., from the 63rd Foot, to be Assistant-Surgeon, vice Foster, who resigns.—93rd Foot: James Webster, M.D., to be Assistant-Surgeon, vice Smith, appointed to the 2nd Dragoon Guards.—Hospital Staff: Assist.-Surg. Thomas Honer Wheeler, from the 2nd Dragoon Guards, to be Staff-Surgeon of the 1st Class, vice Johnston, appointed to the 73rd Foot.

NAVAL APPOINTMENTS.—Surgeons: Daniel Ritchie, to the *Hecate*; Dr. John Smith, to be Surgeon Superintendent of the Ann freight-ship.—Assistant-Surgeons: Frederick Stupart, to the *Spider*; R. P. R. Sparrow, to the *Vindictive*; James Mitchell, M.D., to the *Dolphin*.

APOTHECARIES' HALL.—Gentlemen admitted members on Sept. 23: Henry Lambden, John Thomas Campion, and John Coghlan Haverly.

HONOURS TO MEDICAL MEN.—His Majesty the King of the Belgians has conferred the title of baron on the celebrated Dr. Seutin.

JUBILEE TO M. JACOBI.—At Sigburg, on the Rhine, on the 21st of last March, was celebrated the fiftieth anniversary of the doctorate of Muz. Jacobi, physician to the insane. A great number of eminent physicians assisted at the celebration of this ceremony, on whom it reflected great honour, and also on the Government, who appreciated and encouraged these warm manifestations.

THE NEW SANITARY COMMISSION.—The appointment of the special commission, gazetted this week, for inquiring into the means of improving the health of the metropolis, must be regarded as a recommencement of sanitary reform in a more workmanlike manner. In attempting to legislate, Lord Morpeth was balked by easily foreseen obstacles. In appointing a commission to grapple with the principal of those obstacles, Government stands pledged to a real performance of work. The commissioners cannot mistake their duty or their interest. Three of them are men already versed in their labour. The chairman is a steady, attentive, and judicious man. Mr. Lambert Jones, the commissioner taken from the City, has been called "the representative of filth;" it having been presumed that he would represent the conservative objection entertained in the City against innovation on the vested rights of filth and pestilence to undisturbed away. But the presumption is too gross. We do not remember what precise course Mr. Jones has taken on the subject of sanitary reform; but everybody knows that he is an active, intelligent man, with feelings and tastes above mere local objects. His selection for so important a post cannot but stimulate him to acquit himself with credit; there can be no doubt that he will be a useful aid to the other commissioners, and, possibly, he may be the means of at once dismissing the civic fears of cleanliness, and of conciliating assent. The more boldly and effectually the commissioners do their work, the more thorough will be their support from the public, the more complete their hold on the official concurrence in ulterior measures. It will not be very long before another opportunity will occur for testing the sincerity of the official support. The functions which ought to be performed by a Board of Health are performed, or rather neglected, by certain Commissioners of Sewers, appointed for each district of the metropolis. Except for the City, the commissions are issued by

the Lord Chancellor; and the Chancellor annually appoints them according to a list handed in by each expiring board, which he adopts without question. The commissions will expire in December next. Of course, if the new special commission is to have any practical or reasonably prompt result, it will be needless to reappoint the old machinery for another year. An additional reason against continuing this standing practice is the probability that the commissions about to expire would nominate candidates the most disposed and most able to obstruct the measure intended to supersede them in their functions. The appointment of the commissions, therefore, ought to be suspended at least till the special commissioners have made their report. From the course taken by Lord Cottenham in this behalf, the public will be able to form a tolerable guess as to the official sincerity.—*Spectator*.

TREATMENT OF FEVER PATIENTS.—A person named Patrick Doyle, was brought up at the Police Court, at Newcastle-upon-Tyne, a few days ago, at the instance of Mr. Tullock, charged with bringing one Daniel O'Connell, an Irish labourer, ill of fever, from West Chevington to the parish of St. Nicholas, in Newcastle. Mr. Tullock, who is the keeper of the vagrant-ward, informed the bench that he had been instructed to bring the defendant before them in order to put an end to a system which was attended with great danger to the inhabitants and unnecessary expense to the parish. Some months ago a great number of Irish peasantry had arrived in the district, often in a state of distress, and afflicted with the famine fever, many of whom had been scattered through the county; but it appeared to be the regular practice of the authorities in the district, that as soon as these poor creatures were found to be labouring under fever, it made no matter how far they were off, they were immediately sent to Newcastle, and thus a contagious disease was brought into the very midst of a dense population. The man O'Connell had actually been conveyed in a cart upwards of twenty-two miles, and had thus been cast upon the parish of St. Nicholas. The bench said the case was one of importance, but they were unable to interfere with it. The only remedy was by indictment.

INSANITY AT PERU, MEXICO, TEXAS, AND CHINA.—If we credit the tales of travellers, lunatics are not well treated in South America. At the Hospital of St. Andrew there is always a considerable number. It is open to the public every year, Nov. 30 (St. Andrew's day); and one of the favourite amusements of the inhabitants of Lima is to go and sport with these unfortunate creatures. At Mexico, there used to be a lunatic asylum, but since the last political events it has been used for some other purpose. It appears as if insanity did not prevail much in Texas, as travellers speak very little of it. In China there are very few lunatics, though suicide is frequently committed.

NEW ALKALINE VEGETABLE.—At a meeting of the Chemical Society, a short time since, M. Porrett read an account of the existence of a new alkaline vegetable in gun-cotton, which was called lignine. It was obtained by dissolving gun-cotton in nitric acid at a temperature of from 37° to 74°. In throwing this solution into water, it produces a white precipitate which has all the properties of gun-cotton, but is not fibrous. When this solution is neutralized by carbonate of potash, it gives nitrate of potash in abundance; a precipitate also of a whitish-grey colour, very probably a new carbonate of the alkali. When hyponitrous acid acts upon this liquid alkaline solution, it reproduces immediately hyponitrite of oxide of lignine (gun-cotton). M. Porrett has an idea that the lignine is formed at the expense of the woody fibres, and becomes acid in the sap of the vegetable. Its chemical composition is one equivalent of lignine and two of oxygen.

SMALLPOX IN SHEEP.—A very fatal disease, and, it is believed, new to this country, has lately made its appearance amongst sheep. It is the smallpox of that animal, and in its first stages

more particularly many fall victims to it. It is desirable that the public should be apprized of it, in order that the necessary precautionary measures may be adopted to prevent its further propagation. It was introduced by some Spanish sheep imported from Hamburg, and has already found its way into many flocks. Several sheep affected with it have also been exposed for sale in Smithfield Market. At the Royal Veterinary College experiments have been instituted, by which its infectious and contagious nature have been completely proved, and others are being carried on with a view to check its progress and to lessen its fatality.

DISCOVERY OF PLATINUM IN FRANCE.—M. Gueynard has just informed the General Council of the Isère that he has discovered a vein of platinum in the metamorphic district of the valley of the Drac, which he hopes to work with advantage. Hitherto this precious metal, which combines with incomparable hardness the lustre of gold and silver, has only been met with in the Ural Mountains, and its scarcity has always rendered the price very exorbitant.—*Paris Paper*.

OBITUARY.—Sept. 8th, J. B. McDonagh, Esq., surgeon, at Carrara, of typhus fever, caught whilst in the discharge of his duties.—Aug. 1, at Montreal, of typhus fever, caught whilst attending at the emigrant shed, J. Hutchinson, Esq., M.D., aged 50.—On the 9th inst., after a short illness, aged 49, Thomas Weatherill, M.D., Hunter-street, Liverpool.—Sept. 1st, aged 32, of fever, George Vickers Dunne, Esq., M.D., physician to the Dispensary and Fever Hospital at Clondonagh, Queen's County.—Sept. 4th, of fever, Dr. Lauder, one of the district medical officers in the city of Glasgow.—Aug. 30, at Westport, aged 20, of fever, Peter Lavell, Esq., M.R.C.S. of Engl., surgeon to the Shruel Dispensary.—Lately, at Skibbereen, of fever, Thomas Goodison, Esq., M.D., of Dublin.—At Bolton, aged 28, of fever, Henry Hatton, Esq., medical officer of the western district of Great Bolton.—At Honiton, Sept. 18, Jas. Campbell, Esq., M.D., of a rapid consumption.—At Prince's-street, Perth, Sept. 20, John Monteath, M.D.

MORTALITY TABLE.

For the Week ending Saturday, Oct. 2, 1847.

Causes of Death.	Total.	Average of 5 Summers.
ALL CAUSES.....	1052	940
SPECIFIED CAUSES.....	1047	935
Zymotic (or Epidemic, Endemic, and Contagious) Diseases.....	839	226
SPORADIC DISEASES.		
Dropsy, Cancer, and other Diseases of uncertain or variable seat.....	111	103
Diseases of the Brain, Spinal Marrow, Nerves, and Senses.....	148	157
Diseases of the Lungs, and of the other Organs of Respiration.....	208	226
Diseases of the Heart and Blood-vessels.....	30	26
Diseases of the Stomach, Liver, and other organs of Digestion.....	94	94
Diseases of the Kidneys, &c. (including Diseases of the Uterus, &c.).....	19	10
Rheumatism, Diseases of the Bones, Joints, &c.	6	7
Diseases of the Skin, Cellular Tissue, &c.	1	2
Old Age.....	44	50
Violence, Privation, Cold, and Intemperance.....	37	28

No. 419.

AN ADDRESS

DELIVERED AT THE OPENING OF ST. THOMAS'S HOSPITAL SCHOOL, ON FRIDAY EVENING, OCTOBER 1.

By J. H. GREEN, Esq., F.R.C.S.,
And Senior Surgeon to St. Thomas's Hospital.

GENTLEMEN,—Under the inspiration of hope the spirit within us is quickened to new life and kindled to increased energy: such may be described as the influence which animates us at the commencement of a new session, and, I will add, of a new era of St. Thomas's Hospital School. Nor will it be difficult in reviewing the prospects of our school to justify to its friends, many of whom I have now the honour to address, the anticipation of a future not unworthy of all the great names which have invested the past with radiance and renown. I cannot forget that we owe this brightness to a Cheselden, an Ellis, a Fordyce, a Wells, a Cline, and an Astley Cooper; and, although it is with great humility that we appeal to this great constellation of genius, we trust the appeal will be accepted as a pledge that we propose them as our patterns and guides. But, though I am more than willing to challenge a scrutiny of the qualifications of the gentlemen with whom I have the honour to be associated, any discussion of their merits on the present occasion would be unbecoming, and I am well content to leave the question to the sound judgment of the profession and the public. There are other elements in the eminence of St. Thomas's Hospital on which I may more suitably enlarge, and I fear no contradiction when I say that they consist mainly of the means which it possesses of combining all the requisites of a sound medical education, practical and scientific.

It is true there are other institutions in this metropolis possessing similar advantages, and we have no wish to decri their character and reputation; we wish that they may be greatly successful; but we do assert our claim to a place in the foremost rank, and we do it with a consciousness of large resources for our task, and with the confidence of men zealously united for the great work of professional education. The royal hospital to which we have the honour of belonging—entitled royal in virtue of its foundation by Edward VI.—is proudly distinguished by its noble revenues and the magnificent scale of its charities. Placed in the midst of one of the most densely populated districts of this city of opulence, the palace of Charity, in the Hall of which we are now assembled, throws open its gates at the appeal of sickness and distress. Hither the afflicted are borne from the crowded garrets, the dark cellars, and the unwholesome alleys; from the factories, the warehouses, the neighbouring quays and docks, and from the vessels of all nations which float on the adjacent river. It is here that the gaunt and powerless victim of wasting pestilence, of burning fever, of slow, concealed hectic, of pining atrophy, of ghastly spasm, of suffocating asthma, of evergnawing ulcer, and of the racking torture of stone—all

over whom triumphant Death his dart still shakes, but yet delays to strike, though oft invoked as the chief good and final hope—it is here that the afflicted of all names and descriptions seek and find relief.

It would be, however, but a narrow policy which would confine the benefit to be derived from a hospital to those received within its walls. It is notorious, indeed, that the principal of the charitable institutions in this metropolis of luxury, this home of affluence, are wholly inadequate to supply the wants of its overgrown and ever-growing population. It must never be forgotten that one of the chiefest blessings of the hospitals of this metropolis is the establishment of medical schools in connection with the opportunities which they present for the study of disease. It is only from such schools that the poor of our country, that our army, our navy, belligerent and commercial—nay, that those who have at their disposal the amplest means of remunerating their professional attendants, can be supplied with competent practitioners, since without these means the medical education of the medical aspirant must be gained at the cost of the unhappy victims of unavoidable ignorance and imperfect skill. For very limited, comparatively, would have been the beneficial influence of many of the most illustrious surgeons of the metropolitan hospitals, had their rare abilities been confined to the immediate objects of their skill, instead of being exerted, as they have been, in training successive generations, who have thereby been rendered capable of multiplying the benefits intended by the original founders of those hospitals, by carrying away with them all the happy results of medical study for the relief of suffering, and by applying all the resources of the healing art to the wants of the remotest colony and the humblest village of the wide-spread British empire. I hesitate not, then, to say, that it is the most unalienable duty of those who have the funds of hospitals at their disposal to found, foster, support, and encourage schools for the education, practical and scientific, of medical practitioners. Nay, this duty is little less than urgent and immediate: since it is only by such means that the authorities of hospitals can command a supply of intelligent and skilful officers for those hospitals, the management of which is intrusted to them. But no painful task devolves on me to remind the governors of this hospital of the duties which have been imposed on them; actuated by the humane and generous principles which I have just suggested, they have ever been found foremost in promoting the efficiency and character of medical science in connection with the School of St. Thomas's Hospital. Witness the commodious and substantial building which they have erected for its service; witness, too, the valuable museum; and assuredly the success and character of the school will suffer no diminution under the auspices of our present respected treasurer, who has well recognised that link which connects the interest of the school with enlightened humanity and the welfare of the unfortunate temporary inmates of

the institution; for he will permit me to say, that we owe it mainly to his care, foresight, tact, and management, that the present session opens with brighter prospects and with improved means of success; and he is nobly seconded in his disinterested efforts by the enlarged views and munificent spirit of the almoner, the grand committee, and the body of the governors. If proof were needed of what I have advanced, the evidence might be found in the prospectus of this year. It is not necessary to do more on the present occasion, with reference to that prospectus, than to remind you that prizes are offered in every department of instruction; the substantial fare of education is thus served up with every accompaniment, and in all the tempting varieties that may stimulate the duldest appetite and excite the slowest digestion. Nor must I omit to express the thanks we owe to my esteemed colleague Dr. Roots for the prize offered by him for encouraging the study of clinical medicine. Nor should I forget the offer of the treasurer of a gold medal as a reward for general proficiency and good conduct; and only since I have been within the walls of the hospital this evening have I been informed by the treasurer of another instance of the generosity of our president, who has offered one reward for the best reports of surgical cases, and another for the best medical reports, to be competed for by second year's men. But these are not the only aids and inducements to study; there are other splendid encouragements to professional excellence; the scholarships cannot but tend to sustain zeal and diligence which might otherwise flag under the pressure of long-continued application. The dresserships too, no longer to be obtained by purchase, but reserved strictly as the honours of merit, offer invaluable, I might almost say indispensable, opportunities for forming the character and habits of a thoroughly accomplished practical surgeon. But, beside and, I may say, beyond all this, the house-surgeon will be annually selected from the dressers, and those will be appointed whose qualifications best entitle them to hold an office, the due performance of which will be a lasting guarantee of trustworthiness. Permit me, however, to add, that while offering prizes and honours as inducements to diligence, we should deem them little more than very dear stimulants to pride and conceit, were they offered as substitutes for those better incentives which arise from a lively sense of duty, and which are, therefore, the only reliable, lasting motives to exertion. If moral training, in its indispensable and unavoidable association with religion, be essential to a sound education, it cannot be less dispensed with in a profession which eminently implies moral fitness and the cultivation of that in man which constitutes his permanent worth. The high character of the profession of which each individual is to be the representative; the education and habits of those with whom it should be your ambition to associate, namely, the true gentry of our country, by virtue of liberal education, and elevating pursuits, and moral ex-

cellence; and no less the demands of society at large, dictated by the high degree of civilization to which it has attained in this country; all challenge excellences distinguished by their humanity, and which are, therefore, required of every man, but which no calling is more fitted to elicit, which no calling more imperatively requires, than the medical profession. The authorities of this hospital, entertaining a due regard for the moral welfare of the students committed to their charge, will be actuated by no narrow considerations in carrying out the promise of their prospectus of the advantages of a collegiate establishment. Circumstances over which they have had no control have hitherto delayed the fulfilment of the wishes of those connected with the school, and even now prevent them from fully carrying out the design of rendering the establishment in every respect worthy the name of a college. It would be difficult to appreciate in their full extent the advantages of a system which combines comfort, economy, and discipline, with all the requisite facilities for study; which assembles under the roof of some august edifice, a household united in the ennobling pursuit of science, where the *alumni* during the perilous period of transition from youth to independent manhood are mildly coerced by the same paternal laws, moulded by the same habits of association, influenced by the example of seniors and teachers, and by the estimation of equals, and who ever regard themselves as members of one body forming among themselves a correspondent law of honour, a sentiment of self-respect, and of respect for each other as gentlemen and fellow-collegians. I will fain hope, however, that in whatever degree the collegiate establishment in connection with this hospital shall be perfected, it will not remain a training school for medical students only. I trust I may not be deemed visionary when I assert a conviction that we are founding an institution in which, as in other colleges which already exist in connection with the University of London, the truth will be recognised and adopted of the inseparable fraternity of all the professions—deriving as they do their best honour from the same parentage, and bound by every motive of public duty and honourable interest to the respect, protection, and furtherance of each other's welfare. And if the older universities should still take the lead in the cultivation of the pure and austere sciences, and in the sedulous research of ancient learning, and yet remain the principal outlets of the ecclesiastical profession, it will be the function of the University of London to provide for the cultivation of the sciences which have the forms and productions of organic and inorganic nature as the material, and the application of their laws to the health and well-being of the community in the professions which have arisen or may arise out of them; and among which the medical profession must ever fill the largest space and occupy the most prominent position. It will be the high aim and urgent duty of the University of London to provide for that intellectual expansion which is most in alliance with the wants of the age, and to provide for it in connection with whatever is venerable in our native land; unceasingly occupied in observation and inquiry, and in extending knowledge already possessed; and constantly sending out into the community a succession of labourers competent to apply to the three chief interests—the health, property, and moral well-being of their fellow-citizens alike, capable of becoming, whether in the name of law, medicine, or divinity, in district, town, and village, the germs of civilization—the nuclei around which whatever is of better tendency may crystallize and cluster. Such an institution would exist for the sake of the liberal arts, which acquire and merit that name because they contain as their element a knowledge the attainment of which is its own reward, and which needs no other benefit as a motive for its cultivation. These would be the departments of knowledge by which the professions that have arisen or may arise out of them would be retained in vital

connection with the common trunk of universal science, of which they are ever-growing branches, and of which the circulating sap and the indwelling spirit is the one living truth—the eternal and divine.

But, gentlemen, to return to our institution. The prizes and the collegiate establishment are not the only points to which I will ask your attention. There is another and a noble feature in the arrangements which, as a proof of the wise liberality of the governors, ought not to be overlooked, and is too important in its bearing to be passed by without notice—it is the institution and endowment by the hospital—I say the endowment by the hospital—of a chair of Pathology with clinical duties; and the election, in the first instance, has fallen on my friend and former apprentice, Mr. Simon, whose prize essay on the thymus gland has extended his reputation throughout Europe, and is the first-fruits of the rich harvest that may be expected from his perseverance and originality of mind. It would be, perhaps, most judicious in me to leave the explanation of his office to the professor himself; but I cannot forbear saying even now that the duty of every man aiming at the advancement of medicine to its true place as a science is eminently the improvement of pathology, by obtaining in each instance a clear and precise knowledge, not merely of the coarse and effete products of disease, such as is afforded by a *post-mortem* examination, but a clear insight of the morbid action in which the disease essentially consists. It would be no difficult task to cite a host of cases in which the primal derangement—the proximate cause, as it is called—has hitherto escaped our cognizance, and in which we fail even in distinguishing in those phenomena which we call morbid how much is disorder and how much belongs to the curative efforts of nature—cases in which, therefore, our treatment is blind, blundering, and empirical. This is not, however, the time for the sloth of despair. The advancement of animal chemistry and the increased facilities afforded by the microscope have furnished pathologists with the means of reaping abundant harvests in this hitherto scarcely less than unproductive field of medical study. Ah! we are on the eve of great discoveries for the relief of suffering humanity, and the praise of having forwarded this work will be awarded to the governors of St. Thomas's Hospital, who have wisely established within these walls a pathological laboratory, under the immediate direction of the professor, to initiate researches, not only into the processes by which disease was first established, but also into those curative processes by which it is removed. Let the results be carefully registered, and should the authorities and medical officers of the hospital recognise the advantage—nay, the public duty—as they cannot fail to do, of securing annually authentic records of the experience obtained in this institution; should they cause to be preserved a correct history of the patients treated in the wards, a scientific and accurate statement of every indisputable fact indicative of disease, productive of its termination, and eliciting its cure; should they have completed their task by a periodical generalization of the facts comprehended in these precious documents embodied in abstracts, summaries, and tables; and should other institutions be induced to follow this wholesome example, we shall be possessed of a *liber veritatis* of the healing art by which we may hope to see it rescued from empiricism, and to be ourselves led on to the discovery of laws and causes the knowledge of which will finally invest medical inquiry with all the insight and certitude of science: for, let it never be forgotten that, however distant its actual advancement may be, this is the ultimate aim of every liberal profession, that every duly instructed and accredited member should in his knowledge, and in its application, be an adequate representative of the whole body; that each severally should be capable of applying all the resources of art which the whole can supply; and that the possibility of this must be ever proportioned to the advancement which the art makes towards the exactitude

of a science. And, if the hope of scientific insight must be still delayed in consequence of the limits of our faculties and the varying nature of the subject, where, I pray, can the progress of the student be so well secured as in a great practical school, such as this institution and the few that rival it?—where, alone, the zealous and enlightened teacher is at his command; where a living, ever-shifting cyclopaedia of medical knowledge is continually open; and where the student is led almost without effort to notice, compare, and generalize the facts which constitute medical experience, in order to that knowledge which, to be real, must be self-acquired; and where he may be disciplined to that judgment, skill, foresight, and self-reliance which must ever distinguish the self-dependent master of his art from the mere practitioner or the life-long tyro.

Finally, gentlemen, addressing myself to those who are, or are to be, students of the hospital, let me, gentlemen, earnestly—yes, affectionately—exhort you to take advantage of the ample opportunities here presented, and to pursue your studies with zeal and unremitting attention. You owe this no less to yourselves than to those who afforded you the means of a liberal professional education, and who look forward with anxiety to your success as an ample compensation for their cheerful but, perhaps, not inconsiderable sacrifices for your advancement. Unless you devote your whole heart and mind to this subject, you will never study it with success, nor practise it with satisfaction. Believe me, a knowledge of it cannot be gained by sitting in listless vacancy in the lecture-room, or by sauntering in idle chat through the wards of the hospital, and, after escaping from the restraints of study, passing away the time in idle amusements, or, still worse, by frequenting the haunts of profligacy and dissipation. Pleasures, would you call them?—Yes,

“Like snow that falls upon a river,
A moment white—then gone for ever.”

But, could we suppose that the prescribed forms of study had been passed through—that the appointed examination had been got over by some lucky chance—what would be your situation, when all the responsibilities of practice had come upon you, in your condition of neglected education? Cases would infallibly occur in which, to cover your ignorance and avoid detection, you would descend to the lowest arts; and if by cunning and deceit you could impose on others, you could not stifle the monitor within your own bosom, from which there is no escape nor subterfuge. But the consequences of professional ignorance are generally too obvious to admit of concealment, and you might find it necessary to quit the neighbourhood in which you practised with ruined fortune and blasted character, or you would, perhaps, be held up to scorn and contempt in one of our courts of justice.

But, gentlemen, if you love and prize the profession which you now embrace as you ought, I do not fear that the cases I have supposed will be verified in the experience of any whom I now address. For the attainment of the requisite knowledge, rare genius and talents are not necessary: diligence, attention, and method will fit you for the arduous duties of your profession, and open out your road to fortune and honourable distinction. But, gentlemen, professional knowledge does not include all that we desire from a medical practitioner: need I say that I refer to the moral attainments which are required of you as men, which concern you in an especial degree as medical men, and the possession of which cannot fail to have an important influence in your professional career. I cannot, I believe, give a more correct and comprehensive description of your minor, yet essentially moral duties than is comprised in the maxim:—Think, act, feel, and demean yourselves as gentlemen. The profession to which you are, or are to be, admitted is one capable of conferring honour upon you, and from which you will derive an increase of your own estimation; but, independently of this, I address few who will be so unfortunately

placed in after-life that the character and habits of gentlemen will not be of vital importance to success. The word "gentleman," to every one capable of becoming such, conveys its own meaning so fully that it is almost superfluous to say that he is a gentleman who, in his whole demeanour, shows respect and a due proportion of respect to every one with whom he is brought into relation. This is a feeling of so much importance that I am persuaded that you cannot rightly undertake the duties intrusted to you unless you are influenced by its sentiment, which will manifest itself as you recognise, on the one hand, the respect due to man as a human being, and on the other, the particular rank to which each individual is entitled by the established laws of society. The suffering incident to human nature, which it will be your office to soften and remove, will, at times, constrain the highest to treat you as their equals; and you will be undeserving of the name of men, much more of gentlemen, if the sight of the same suffering—the forerunner, perhaps, of death in levelling the artificial distinctions of society—do not induce you to treat the lowest as brethren.

ABSTRACT

OF AN

OPENING ADDRESS

DELIVERED AT THE HUNTERIAN
SCHOOL OF MEDICINE, OCT. 1, 1847.

By C. J. B. ALDIS, M.D. Cantab.,

Fellow of the Royal College of Physicians, and Physician
to the Metropolitan Free Hospital.

GENTLEMEN—It is under very painful circumstances that I act as a substitute for one who for the last twenty-five years had been in the habit of delivering an opening address to the pupils of this school. He had already commenced the business of the present session, vainly believing that he would recover, and was anxiously looking forward to perform that duty which I am unexpectedly called upon to undertake, when death snatched him away, depriving you of one of the most eminent anatomists of the present day. Mr. Dermott was the favourite pupil of the late celebrated Joshua Brookes, who entertained so high an opinion of his qualifications that Mr. Brookes placed a son, as house pupil, for two years under Mr. Dermott, who superintended his surgical education until he passed the college. The shock occasioned by Mr. Dermott's death greatly affected his widow and friends, and the last act of his life was to place the superintendence of the school upon me. There were vacancies to be filled up, and numerous arrangements to be made, very little time remaining before the commencement of the session to accomplish this object, so that death had not only deprived the principal of this school of his life, but had nearly destroyed, if I may so speak, the vitality of the school itself; but, through activity and perseverance, our little bark is again afloat, and will continue so, I hope, for many years. As a lecturer on anatomy Mr. Dermott was most popular: his demonstrations, also, will long be remembered by those who had the benefit of his instruction. I have said that he was most popular, and deservedly so, for his regularity in lecturing, the facility with which he made himself understood by the meanest capacity, and for the zeal with which he endeavoured to infuse knowledge into the minds of his pupils. So anxious was he to fulfil his duties as a lecturer, that, even when suffering from illness, he would perform them; and I have seen him frequently carried in and out of the lecture-room by the pupils, being unable to walk in consequence of some bodily ailment. What vigour and animation appeared while he was lecturing—what amusement and what roars of laughter he excited at the examinations, without losing sight of their importance! At the same time he was a strict disciplinarian in the school; but, if any of you should have thought him occasionally too severe,

reflect for a moment that he intended well for you—reflect, also, upon the vicissitudes of his fortune; and, above all, the organic disease with which he was for years tormented.

A biographical sketch of Mr. Dermott having already appeared in the *Medical Times*, I would merely allude to one anecdote, not mentioned there, which struck me so forcibly that I entered it into my note-book, from which I make the following extract, dated August 21 last:—"I called upon Dermott again after he had left his bed, at the time he thought he would recover, when, to my surprise, he touched upon the subject of religion with an intensity of feeling for which I was quite unprepared. He thanked God for his mercies, in having been so kind as to spare one who had so long neglected religion; he dwelt upon the danger of a mere death-bed repentance, and, with tears in his eyes, spoke fervently, eloquently, and thankfully, for their having been opened, through Jesus, to the consolations of religion. He then dwelt upon the justification of a sinner through faith, and upon the iniquity of unrestrained conversation. At length he rose from the sofa, and pressed his hands upon his head, becoming almost frantic with despair. Mrs. Dermott and myself endeavoured to assuage this excess of grief. He alluded to the impossibility of his being forgiven; at the same time he felt most grateful for the light that had shone upon him. I endeavoured to point out the forgiving spirit of the Deity, even under extreme circumstances, and related the story of the Pharisee and the Publican. He became more resigned; and, in conclusion, hoped that some of his friends would be brought to a sense of religion—that their thoughts might be diverted from the vanities with which they are surrounded, and be brought to the contemplation of a future state. He prayed fervently with the Hon. and Rev. Montague Villiers, Dr. Beaumont, and Mr. Stanley, who have assured Mrs. Dermott with the hope that your late unhappy master is now in a state of happiness. The above gentlemen, as well as his medical attendants, Dr. Prout and Mr. Stafford, did everything in their power, spiritually and medically, to assuage his sufferings, which were at last terminated on Sept. 12—the fatal complaint being thickened bladder and diseased kidneys, of a chronic character, supervening upon an old standing stricture.

Mr. Dermott had intended to insure his life, but, like many scientific men, neglected to do so, and has in consequence left his widow totally unprovided for. She has nothing certain at present, except the annuity of £30 from that admirable society, the Society for the Relief of the Widows and Orphans of Medical Men. The lecturers of this school intend to allow her a portion of the proceeds, so that she will have an interest in the success of the establishment. In this sad and short picture there are many circumstances to be dwelt upon with advantage:—1. The being carried off in the prime of life at a time when Mr. Dermott was looking anxiously forward to be most occupied. 2. The postponement of religion to a late period of life. 3. The leaving a widow totally unprovided for. 4. The termination of the complaint. But I do not intend to dwell upon them, hoping that you will ponder over them again and again, for we know not how soon we shall be called away by death; but this we know, "to the same complexion we must come at last." I have not mentioned these subjects because I wish to find fault—it is painful to do so—but I feel deeply the responsibility of my position as superintendent of this school, and I must look to your welfare in every point of view. Too often any allusion to religious matters is voted a nuisance, or it may be called cant, or something worse, but it is "the one thing needful," and I would implore the pupils of this school to elevate their minds from the carcass they dissect to the Deity who made it. Be most expert anatomists if you please, but be not puffed up with mere attainments in any science; there is something beyond science which our philosophy will not easily explain.

I would say a word or two about the termination of Mr. Dermott's disease. We were looking forward to coma or convulsions as a probable ending to his complaint, neither of which happened. Might not this be an interposition of Providence, warding off the frequent termination of this disease, allowing his senses to remain perfect to the last moment; and, consequently, more time to be devoted to prayer?

The lecturer then alluded to the grandeur obtained by those nations in which the arts and sciences flourish, and how much the fate of youth depended upon the cultivation of the mind. The great truths which medical men were bound to investigate nourished and strengthened the mind and enlarged the ideas. Study excited the mind to emulation, by which it was encouraged to hope for success. It rendered us useful to mankind, attracted the mind from idleness and dissipation, and urged it on to contemplate facts and give correctness to the reasonings upon them. He hoped that students would not be discouraged by the difficulties which met them at their entrance into the profession of medicine; and, in alluding to different plans of education, quoted the words of Dr. Latham respecting "the necessity under which the majority find themselves of exercising their profession early requires that they should be made practitioners in the easiest and nearest way. Their knowledge should be of things obviously necessary, and this knowledge ought to be rigidly exacted, and nothing more." It is scarcely necessary for me to dwell on the importance of the medical profession, the origin of which had been ascribed by Cicero to the invention of the immortal gods. When we consider the various branches of study that are either useful or actually requisite in order to understand our profession properly, it must be obvious that an unremitting attention should be exerted by us to obtain this object. A knowledge of polite literature, the classics, and the modern languages, were justly among the prerequisites of a medical education. The mathematics, also, will strengthen the mind and prepare it for the investigation of truth. How many absurd theories are frequently found in medical writings! How many vague hypotheses have been started in regard to the proximate cause of fever! Again, the essential cause of inflammation has been a bone of contention for ages. Although medicine and surgery are intimately connected and are to be considered as branches of the same root, still, as division of labour tends to improvement, no doubt advantage is derived in an art so difficult and extensive from the distinction of the physician and surgeon; but it is necessary to understand the principles of both before eminence can be obtained in either.

The lecturer then devoted a great portion of his discourse to the consideration of the different sciences which must be studied during a course of medical education, of which anatomy and physiology were the bases; chemistry and botany were auxiliary sciences; then pathology and practice of physic, surgery, *materia medica*, widwifery, and forensic medicine. Be not alarmed at the large volumes written on *materia medica*, for it is not necessary to get them by heart "*totus blaterantes pharmacopoeias*," but it will occupy much time at the bedside of the sick to learn those remedies which are useful for the cure or alleviation of disease. Be not, however, vast experimenters, especially with new remedies; recollect there are various fallacies with regard to cause and effect. Few can have observed the fate of a number of useless and dangerous remedies which have been introduced without regretting that a certain degree of scepticism did not exist with regard to their alleged efficacy. Remember that you are guardians of the public health, and that you cannot be too cautious in adopting new and potent medicines. Observe their effects carefully and with a true philosophic induction—that is, *pro* and *con*, and deduce inferences with the greatest regard to truth. It is greatly to the honour of the medical profession that it has always been ready and active to adopt sanitary measures for the public safety. When the plague

or cholera, or any other pestilence, prevailed, medical men, at the hazard of their lives, have visited the sick while others fled in alarm. The plague of London, in 1665, is computed to have carried off 100,000 individuals. Is it not, therefore, necessary that a medical man should be among the foremost in adopting sanitary measures for the health of the public; in encouraging free ventilation, drainage, and cleanliness wherever they should be neglected; by doing which he may render himself a benefactor to his species? Mr. Chadwick has stated, in his Sanitary Report, published in 1812, that "A conception may be formed of the aggregate effects of the several causes of mortality from the fact, that the deaths caused during one year, in England and Wales, by epidemic, endemic, and contagious diseases, including fever, typhus, and scarlatina, amounting to 56,461, the great proportion of which are proved to be preventible: it may be said that the effect is as if the whole county of Westmoreland, now containing 56,469 souls, or the whole county of Huntingdonshire, or any other equivalent district, were entirely depopulated annually, and were only occupied again by the growth of a new and feeble population, living under the fears of a similar visitation. The annual slaughter in England and Wales from preventible causes of typhus, which attacks persons in the vigour of life, appears to be double the amount of what was suffered by the allied armies in the battle of Waterloo." It was presumed that the Government would have been able to effect something during the last Parliament for the sanitary condition of the people. It made strenuous efforts to accomplish something. Lord Lincoln's bill contained remedies for the removal of enormous evils destructive of the comfort, the morals, and life of numbers of the people. Valuable reports have been presented to the Legislature and public on this subject in 1838, which were followed up, and in 1843 by her Majesty's commissioners, appointed "to make further inquiries into the actual state of large towns and populous districts, and to devise the best means of promoting and securing the public health." The result of these inquiries has been a body of evidence of the highest order. Do the opponents to sanitary reform know what they are about? Did they ever suffer from fever themselves? Look at these plates in which you see delineated the ulcerations of the intestines—a common result of fever. I have seen the intestines perforated like a cullender from this cause. Again, the brain may become inflamed and disorganized, producing palsy or mania, or the respiration may be impeded by inflammation of the lungs during fever; so that a person may be tormented for the rest of his life by organic disease through fever; and yet there are to be found persons who oppose legislative remedies for the removal of such an intense evil.

I attended a case of fever a short time ago in Juniper-court, near Barclay's brewhouse; during my visit, I learned that fever had existed in nearly every house. The place was most offensive from an untrapped gully-hole in the centre, accumulations of filth, and the stables, in addition to which the supply of water had been taken off during the day, and was only put on at uncertain times of an evening. Is it surprising, then, that we are called upon to attend erysipelas, gastric irritation, asthma, and fever, occurring in the same family one after the other, when they are compelled to reside in such dens? A visit to Redcross-court and Maypole-alley, in the Borough, would surprise some of you. I have dwelt upon this subject, for I feel greatly the importance of medical students paying attention to the subject of hygiene.

The lecturer then called their attention to some diagrams of differently-formed sewers, traps, and gully-holes, contrivances to prevent smoke and other matters relating to sanitary measure.

You may, however, be excellent anatomists; you may, also, be skilled in all the sciences previously mentioned, and yet not be good medical

practitioners. There is still something wanted to crown all this, to constitute a skilful person—something which will enable you to distinguish diseases and apply judicious remedies. It is clinical practice, which can only be acquired in the wards of a hospital. If you neglect this important branch of your profession, you will feel greatly at a loss whenever you are called to the bedside of a patient. It is true that a few simple cases may require very little treatment, and the patients recover; but diseases are liable to become complicated—look, for instance, at this greatly enlarged heart, which occurred in connection with acute rheumatism; it would be very dangerous to overlook such a complication as this, arising from rheumatism.

Many other illustrations were then introduced to illustrate complicated diseases, and the necessity of great attention to clinical studies.

You should, therefore, see disease in hospitals and dispensaries; in the miserable and comfortless hovels of the poor, as well as visit the sick-bed of those in higher stations. Some students are disposed to think that their studies are terminated when they have attended clinical medicine; but medical men should never cease to study, for new facts often occur in medicine which puzzle even the most learned practitioners; and this should teach us to be charitable towards each other, and not to imagine that we could always have devised better means where another has failed to relieve a particular case. Be careful to keep your minds unprejudiced by theories; diligently examine facts for yourselves; note cases at the bedsides of the patients, make remarks upon them, and draw your own inferences; at the same time be careful of becoming either dogmatical or too sceptical while performing this duty. Follow the principles of inquiry which have been established by Bacon, so that your minds may be fitted for the diligent investigation of facts, unprejudiced by preconceived opinions. You will frequently have occasion to act on the spur of the moment in a dangerous case; there will be no time for delays; delay might be death. How valuable your clinical knowledge will be then, if you have availed yourself of every opportunity to obtain it! Besides, you may, when early established in practice, be called to a dangerous case; you may have to decide before an anxious family respecting its nature and treatment; you may be succeeded by older and more experienced practitioners, who will be able to detect any glaring mistake which might have happened. In other professions there is an opportunity for retreating to authority; in most cases you will be unable to do so, hence your minds should be habitually directed to the study of your profession in order that you may acquire sagacity in distinguishing, and expertness in treating, disease. It would be better to observe the cases in the wards for a short period before recording them; make inquiry into the symptoms; examine, by means of the stethoscope, the condition of the heart and the lungs in a state of health, in order that you may be able to detect any derangement of their functions during disease. If you were to inquire into the history of the most eminent medical practitioners of the present day, you would find that they adopted this method—that in their younger days they were constantly in the wards of the hospital, watching and noting down for themselves the symptoms, progress, and results of diseases; in a word, they were diligent clinical observers. By pursuing this plan you will have in your possession a clinical system of practical medicine that will be useful to you for the remainder of your life. But personal experience will not alone suffice: it will be necessary for you to read much. It was well said by Dr. Cull, when an objection was made by the bench to witnesses for referring to medical authors, "My lord, it must be reading, as well as a man's own experience, that will make any one a physician, for without the reading of books in that art, the art itself cannot be attained to." It is well to add, observes Beck, that he was allowed to proceed. Again, it is mentioned in the Lectures of Mr.

Amos, that a medical man flippantly replied to a question, by slighting the information which was to be obtained from medical writers, saying that the writers of books would advance anything. Chief Justice Dallas reprimanded the witness, and remarked that he would not sit in a court of justice and hear science reviled, and the recorded researches of the medical world represented by ignorant tongues as leading only to uncertainty.

However learned an education the kindness of your parents or friends may have bestowed upon you, should you have already made great progress in your preliminary education, it will be of little value unless you diligently observe for yourselves at the bedside of the sick. Honour will not cure a fever or set a leg, "therefore hath honour no skill in surgery" or medicine. I by no means wish you to undervalue preliminary studies, but I cannot conceal the truth, that your former knowledge, or even the acquisition of those sciences above alluded to, will not alone qualify you for the cure or alleviation of disease. On entering the medical profession frequent complaint is made that there is very little chance of success, because so many persons are embarked in it. Might not the same objection apply to every profession—to the church and to the bar, or any other occupation? Try any employment and you will find that there are plenty of candidates for it. Recollect that by steadiness, attention, and perseverance, by great regard to moral character in a profession in which confidence must necessarily be reposed in you, the difficulties which at present appear insurmountable will be overcome. Consider also the advantage of

one settled occupation; the sons even of kings are educated to one of the professions. Would you envy the street loungers, the careless, the dissipated, the do-nothings? There are two paths for you to choose—the one straightforward and honourable; the other dangerous, leading to ruin, disease—leaving, perhaps, not a cranny in your bodies free from it, and probably a premature death. It has been truly said by Goldsmith, that the most usual way among young men who

olution of their own, is first to ask one friend's advice, and follow it for some time; then to ask advice of another, and turn to that; so of a third: still unsteady, always changing. However, every change of this nature is for the worse. People may tell you of your being unfit for some peculiar occupations in life, but heed them not; whatever employment you follow with perseverance and assiduity will be found fit for you. Life has been compared to a race; but the allusion still improves, by observing that the most swift are even the most apt to stray from the course.

To know one profession only is enough for one man to know. Be contented, therefore, with one good employment, for if you understand two at a time, people will give you business in neither. In illustration of the above statement, Goldsmith relates the following story. A conjurer and a tailor once happened to converse together. "Alas! cries the tailor, what an unhappy poor creature am I! If people ever take it into their heads to live without clothes I am undone; I have no other trade to have recourse to." "Indeed, friend, I pity you sincerely," replies the conjurer; "but, thank Heaven, things are not quite so bad with me, for if one trick should fail, I have a hundred tricks more for them yet. However, if at any time you are reduced to beggary apply to me, and I will relieve you." A famine overspread the land; the tailor made a shift to live, because his customers could not do without clothes; but the poor conjurer, with all his hundred tricks, could find none that had money to throw away; it was in vain that he promised to eat fire, or to vomit pins; no single creature would relieve him, till he was at last obliged to beg from the very tailor whose calling he had formerly despised. Sink not, therefore, into sotti-h indifference, producing a mental atrophy. You may not possess the wealth of the rich man, but you may avoid his diseases from repletion, by activity of mind and body, and

render yourselves, as far as men can be, independent!

Dr. Aldis then alluded to the medical staff of the school, and stated that he had received promises of their cordial co-operation for the future management of the establishment. The museum had been greatly increased by an addition of preparations; and he concluded by saying that every endeavour would be made to render the courses of instruction as complete as possible, with due regard to the convenience of the classes, and that his colleagues and himself would be anxious for their increase in professional knowledge, and growth in valuable acquirements.

The lecture-room was completely filled.

DUMAS ON ORGANIC CHEMISTRY. No. XXXI.

(Continued from page 625.)

Extractive Matters soluble in Water only—That portion, which alcohol at 0·833 is incapable of dissolving, constitutes an opaque brown mass, having an agreeable taste of broth or meat. This substance possesses an alkaline reaction, and contains lactic acid in a peculiar state, in which it is but slightly, if at all, soluble in alcohol. It, moreover, contains some extractive matters, which M. Berzelius has endeavoured to separate one from another, and among which we remark a peculiar substance which has received the name of *comidine*.

To procure this matter, we dissolve in water the residue of the treatment by alcohol, and turn into the liquor some ammonia and acetate of baryta. A precipitate of phosphate of baryta takes place, accompanied with some animal matter. This solution is to be filtered and perfectly neutralized by means of acetic acid, after which it is to be precipitated by the neutral acetate of lead, taking the precaution to neutralize by ammonia the acetic acid which becomes free. The precipitate is to be washed, diluted with water, and decomposed by sulphuretted hydrogen. It is then to be left at rest for some time, so as to allow the sulphuret of lead to deposit, and finally to be filtered. This solution is of a brown colour, and is not decolorized by animal charcoal. It still contains a little lactic, and some hydrochloric, acid, which should be removed by evaporating the solution and treating it by alcohol, which does not take up the extractive matter.

It possesses the external properties of a brown extract, which hardens by desiccation, but does not otherwise change in the air. It has a strong and agreeable taste of meat, which perfectly resembles that of the matter yielded by fibrine to boiling water. Placed over the naked fire, it swells up and emits an animal odour. It is dissolved in water in all proportions, but is precipitated from it by alcohol. Alcohol at 0·833 dissolves, however, sufficient to acquire a yellow colour.

The acetate of lead, the nitrate of silver, and the chloride of zinc, precipitate it from its aqueous solution. The precipitate formed by the acetate of lead is slightly soluble in water; that which we obtain by the subacetate is altogether insoluble in that vehicle. Carbonic sublimite and the infusion of gallnuts do not precipitate it when pure.

The filtered liquid, which we obtain in the preparation of *comidine* by means of the acetate of lead, yields a white precipitate on the addition of the subacetate of the same base; this precipitate, when washed, and decomposed by sulphuretted hydrogen, gives to water a colourless matter, which possesses the aspect and taste of gum, and which does not exhale any animal odour when burned.

Lastly, the liquor, on being separated from this latter precipitate, and decomposed by sulphuretted hydrogen, holds in solution a colourless substance mixed with some acetates, and which turns yellow during evaporation.

We thus see that the extractive matters of the meat, which M. Berzelius has taken so much

pains to isolate and to place in their true light, are of considerable variety; but still we must acknowledge that none of them possess any clearly defined characters. It is, indeed, exceedingly probable that some of the principles which he regards as pure, are mere mixtures of several other matters.

We shall terminate this subject by giving a few analyses of muscular tissue:—

	Berzelius. Ox.	Bracconnot. Bullock's heart.	Schlossberger. Ox.	Schutz. Ox.
Water	77·17	77·03	77·50	77·50
Fibrine, cellular tissue, nerves, and other matter of the blood	2·70	18·18	17·50	15·00
Albumen and coagulating matter of the blood	2·20	2·70	2·20	1·30
Alcoholic extract and salts	1·80	1·91	1·50	1·32
Aqueous extract and salts	1·65	1·15	1·30	1·80
Albuminous phos- phate of lime	0·08	—	trace	—
Fatty matter and loss	—	—	—	0·08

M. Schlossberger has examined the muscular tissue of the fish, and has found it to be less rich in solid materials. The following are the results he obtained:—

	Carp.	Trout.
Water	89·0	80·5
Fibrine, &c.	12·0	11·1
Albumen, &c.	—	4·1
Alcoholic extract and salts	1·0	1·6
Aqueous extract and salts	1·7	0·2
Albuminous phosphate of lime	—	2·2

Pus is a more or less viscous, yellowish liquid, having peculiar faint odour and a sweet taste, and which is secreted by the surface of a wound, or by an inflamed organ. That which is formed on the surface of certain ulcers, or wounds complicated with necrosis or hospital gangrene, is more fluid, and exhales a repulsive, fetid odour; this is unhealthy pus.

Healthy or laudable pus is moderately viscous. According to M. Gueterbock, its density is about 1·03. When preserved from contact with the air, it is ordinarily neutral to litmus-paper. That which is secreted by the surface of a healthy-looking wound may at present the neutral reaction still, it is not an uncommon thing to find it acid. The pus of leucorrhoea reddens litmus paper. Frequently, pus is alkaline; when it is of a bad nature it usually presents this character, which is owing, in such case, to the presence of a little ammonia. M. Donné has proved that the pus in gonorrhoea is, in the male, ordinarily alkaline. M. Gueterbock made a similar observation on pus taken from the surface of several wounds and ulcers, and he discovered that this alkalinity frequently disappears to give place to an acid reaction. He attributes this change to the formation of a little acetic or lactic acid.

Pus mixes with water without being dissolved, but forms with it a true emulsion, very different in this respect from mucins, which never admixes itself with that fluid. It offers great difficulty, for the matter which is added in suspension in it, speedily blocks up the pores of the paper. The filtered liquid coagulates on heat, a evident proof that it contains albumen. The proportion of this principle is not, however, very great, for the coagulum is never very compact. It appears, moreover, that the albumen of pus, as well as that of the serum of blood, possesses the power of resisting coagulation by ether.

Filtered pus is precipitated by acetic acid. According to M. Gueterbock, it owes this property to a principle analogous to caseine, and to which this physiologist has given the name of *pyine*.

To isolate this substance, and make a perfect analysis of pus, M. Gueterbock operated in the following manner:—He heated some pus with rectified alcohol, and filtered the liquor while hot. On cooling, there was formed a deposit of fluid matter, fusible at about 60°, which communicated a stain to paper, and burned with a

yellow flame, at the same time disengaging ammonia. From these characters, M. Gueterbock does not hesitate to regard this substance as a fatty body, although he has never succeeded in saponifying it; and, furthermore, the presence of nitrogen in this matter would seem to indicate that it was a body of a different nature, or at least that it contained, in a state of admixture, some azotized principle. However this may be, M. Gueterbock affirms that it contains no cholesterine.

The alcoholic solution, on being separated from this matter, was evaporated and treated by water. This liquid became charged with an extractive matter (*osmazome*), the ashes of which were found to possess an alkaline reaction, and which probably contained some lactate of soda. The residue was formed of a matter having a fatty appearance, similar to the foregoing, and, like it, non-saponifiable.

The part insoluble in alcohol was reacted on by water, which left a residue formed of coagulated albumen and globules of pus. The aqueous solution contained, besides a little albumen, which could with facility be coagulated by heat, and separated by filtration, the *pyine* of which we have just been speaking. The following are the principal characters which M. Gueterbock assigns to this substance:—It is insoluble in concentrated alcohol, and soluble in water. This solution is precipitated by acetic acid and by alum; an excess of these reagents does not redissolve the precipitate. The yellow prussiate of potass forms no precipitate with it; by the addition of a drop of hydrochloric acid to the liquor, a deposit is thrown down which disappears in the slightest excess of acid. The solution of pyine, when acidulated by hydrochloric acid, does not form a precipitate with the prussiate of potass. Caseine, with which pyine has otherwise so great an analogy, behaves in a totally different manner with this reagent. It is equally impossible to confound *chondrine* with pyine: for the former of these substances furnishes gelatine by ebullition, and gives with the solution of alum a precipitate soluble in an excess of this reagent—characters which do not belong to pyine.

Notwithstanding the knowledge of these properties, the chemical history of pyine is yet far from complete; so that we cannot justly place it among the number of those substances of which the characters may be said to be thoroughly defined and understood.

Pus contains all the salts which are to be found in the other liquids of the economy; M. Gueterbock succeeded in determining them by incineration.

The following are the results of the analyses which he made on some fresh pus:—

Water	86·1
Fatty matter soluble in hot alcohol	1·6
Fatty matter soluble in cold alcohol, and extractive matter	1·3
Albumen, pyine, globules	7·4
Loss	0·6

The above pus left, on incineration, seven per cent. of soluble salts, formed principally of chloride of sodium, and one per cent. of phosphates and earthy carbonates, with some traces of iron.

The results obtained by M. Valentin differ from the foregoing. This physiologist asserts that he has found in pus, cholesterine, stearine and oleine, results which would appear doubtful, if we may judge by the experiments of M. Gueterbock.

Does pus contain fibrine? Some observers, and in particular MM. Valentin and Mandl, have resolved this question in the affirmative, and think that the lobules and granulations which we find in pus really contain fibrine. Still, this opinion is founded on no very positive chemical datum.

Ammonia, when mixed with pus, gives rise to a characteristic reaction, first pointed out by M. Donné. The mixture loses its fluidity, and assumes the appearance of a more or less transparent, yellowish jelly, which may be drawn

out into filaments. This reaction may serve to distinguish pus from some other liquids, and especially from mucus; it is due to the swelling out of the globules which swim in the pus, and of which it is easy to prove the presence by means of the microscope.

In fact, when observed under a suitable lens, pus presents itself under the form of a serous liquid, in which are seen to be swimming globules of various forms and sizes. The greater number are double the size of those of the blood; they are pale and more transparent than are these latter, and their form is less regular. Sometimes, they are pretty well rounded and smooth; at other times, their surface is rough and uneven, or flattened, and offers angular projections of great irregularity. According to M. Gueterbock, they are composed of an envelope of albuminous matter, soluble in acetic acid and precipitable by prussiate of potass, and of a nucleus formed of granules which are insoluble in the acids.

More recently, M. Bourguignon has made a very curious and important observation upon the constitution of these globules, should it turn out to be confirmed. On diluting some pus with a little water, and observing one of the globules intact, he remarked that the granules, or corpuscles, contained in this globule, were animated with a very rapid movement; one might say, in fact, that the vesicle was filled with a host of animalcula; when the external membrane was ruptured, these animalcula escaped, at the same time preserving their power of motion. Acetic acid instantaneously arrested this phenomenon.

We may also add, that M. Borelli and, subsequently, M. Donné have proved the presence of *ribribiones* in the pus arising from chancre, and that other observers have found various infusoria—as *monades* and *vorticelle*—in pus of a bad nature; these, however, are secondary results which we must not confound with the foregoing.

Fetid pus differs in no sensible manner from laudable pus, in so far as regards the appearance of the globules. The putrid decomposition appears to exercise itself only upon the matters dissolved in the serum. Beyond the formation of ammonia, it gives rise to the production of a very appreciable quantity of sulphuretted hydrogen, proceeding from the sulphur of the albuminous matters. We can thus readily understand the presence of hydrosulphate of ammonia in unhealthy pus, and we may further explain the black tint assumed by the surface of certain wounds, or communicated to the dressings applied to them, on making use of goulard-water as a topical application.

ORIGINAL CONTRIBUTIONS.

OBSERVATIONS

ON CERTAIN SURGICAL PRINCIPLES AND PRACTICES,

By F. C. SKEY, Esq., F.R.S.,

Lecturer on Anatomy to St. Bartholomew's Hospital.

It would be a curious subject of inquiry, and not unprofitable withal, that which would recall to the attention of the practitioner of medicine, to whatever grade of the profession he belongs, the source of the opinions on which are founded his future views of disease—whether they have been the legitimate offspring of conviction, founded on unprejudiced inquiry, on a close scrutinizing observance of the real workings of the machine; or whether the issue of a sort of godfather adoption of the opinions of others, by such as timidly prefer an authority to a reason; or thirdly, of those who, entering on the wide field of investigation, place interest before truth, and attach themselves to that standard which has fewest adherents, in the hope of early promotion to the leading ranks; or, fourthly, of those few who, swayed by no prejudice, captivated by no theory, and seduced by no authority, adopt opinions simply because they are

in direct opposition to all theory and all authority—of those who display their own standard, to the eccentricity of which they trust for their notoriety.

It would be a curious inquiry, and not unprofitable, to observe how far opinions which may be supposed to influence the welfare of so many, result also from character and personal feeling. If the hard maxims of law may be twisted by political bias, even by the judicial administrator of the law on the bench (and who will doubt it), can it be expected that medical men should be exempt from influences inherent in our very nature and bound up with our most sacred affections? If any science will justify variety in opinion, it is that of medicine. Its uncertainty and the inefficiency of its immediate agents, so long as minds will speculate, justify, even among the most logical and the most philosophical practitioners, differences wide and various. But such differences, wide and various as they present themselves to the unreflecting, should be but differences of detail; the principles, for the most part, should stand prominent and demand obedience. The true principles of medicine are, of course, based on a true physiology. This ought to be the framework of our practice and our opinions.

The foregoing remarks have arisen from occasional rumination on the state of the profession, as seen through the varieties in the views and practice of its various members. The cause of the difficulty in determining and selecting the treatment most appropriate in the cure of disease arises from the fact, that the large majority of diseases in reality advance onwards to their own cure, sometimes hand in hand with, and often in despite of, treatment. Thus the degrees of excellence in practice and the soundness of opinion are determined with difficulty, for it is chiefly in the niceties of management of disease that the able practitioner manifests his superiority. But these very points of detail, in reality so important, are so minute and so delicate as to be inappreciable by the eye of the unthinking, who find success of a certain kind the attendant on their own views, and, in their ignorance, refer the cure to their treatment, rather than to nature.

The higher the class of practitioner, and the greater his experience, the more does he lean on Nature for his guide, and less and less confidence does he repose on the curative influence of medical agents. The sound practitioner of medicine follows Nature as his polar star. If she be distorted from her path, he endeavours to conciliate her by gentle means to a return: he studies her movements and strives to imitate them.

In the great varieties of treatment of the present day none is more striking, and perhaps more characteristic of the man, than that which, referring a large class of diseases to inflammatory actions, professes to remedy them by reducing the quantity of the circulating blood. Such a man's reliance is on the lancet, which is ever employed with an unsparing hand; and on purgative medicine, which forms the staple of his stock. He deals largely in calomel, in black doses. He abjures nitrogenous principles, and every nutrient element, lest they add to the inflammatory liability of his patient. He bleeds in headache, he bleeds in pleurodynia, he bleeds in gastrodynia, he bleeds in rheumatism and in gout, he bleeds in hemorrhage, and when in difficulty or in doubt still he bleeds. He argues that the loss of fifteen or twenty ounces of blood will do no harm to the health of the individual, and "he rarely loses a patient." He is called to an accident. It matters little what its nature. He bleeds the patient to ensure his safety; he professes no farther motive than that of preventing inflammation. In injuries to the skull or brain, twenty ounces of blood are abstracted. "The pulse rises," says he, "and I bled him again." Thirty years since, bleeding to fainting was recommended by authority, and was unhappily adopted by many, for acute inflammation of the conjunctiva. For a thousand years and more, pain, heat, redness, and swelling, have con-

stituted inflammation; but, with this class of practitioners, any one of the above signs appears to justify the lancet. In truth, their depletions are confessedly not restricted to inflammation, but are resorted to in aid of general treatment. How far are such views of the nature of disease removed from those of the most enlightened and the most experienced members of our profession! What is the immediate effect of bleeding on the pulse of a person, not the subject of positive inflammation? It rises, as it is called; that is to say, it becomes more frequent in its beats; and, supposing the quantity of blood taken to be large, it is no longer a tonic pulse, but is unnaturally soft and compressible. It has been raised ten or twenty beats in a minute, partly in obedience to the wants of every part of the body, which calls for blood from the central supply; and partly because, the force of contraction of the heart remaining nearly the same, it has a less duty to perform. The frequency of the pulsation is proportionate to the reduced quantity of blood. The exceptions to this rule are rare and peculiar.

The effect of loss of blood on the system is a sense of languor and loss of power; on the bowels, constipation. Select a healthy man of forty, the regular action of whose digestive system has been his boast throughout life; abstract twelve or sixteen ounces of blood from his system, and the action of his bowels is suspended until the blood removed from the circulation has been replaced by the extra work thrown upon the lacteal system. Does Nature take no cognizance, then, of a sudden diminution of the circulating blood? and does the necessary consequent constipation mark her approval or otherwise? But of infinitely more importance to the recovery of the individual is the condition of health of the nervous system. If the circulation be accelerated by loss of blood, if the tonic pulse be rendered compressible and soft, does not the nervous system participate in the injury? Unhappily, the workings of this important element of health are not so palpable. They cannot be tested by the finger, like the circulation; they are detected in their minute manifestations only by the observant and the reflecting, and most assuredly they often escape observation by the medical community.

They may be seen in the actions of the eye, and in the expression of the countenance; in the heavings of the chest, in the action of the muscles, and in the attitude of the person. They may be felt in the pulse, in the insubordinate beatings of the centre of the circulation, and in the skin. They may be deduced from the altered tone of the mind. They may be so detected. But are they? Do not these phenomena, all-important as they are, frequently pass and re-pass before the eye of the practitioner without remark; or, if observed, are they understood to an extent which influences his treatment? They may be freely developed by bloodletting, employed without the protective agency of inflammation. They may be developed through the agency of poisons, as in fever, &c. Under any circumstances, they are evidences of a wrong sustained to a system as important to life as the heart itself. Exactly in proportion to the quantity of blood removed from the circulation is the nervous system disturbed. It is no longer tonic. It exhibits itself in a variety of forms of fitfulness and eccentricity. The actions of the circulation are under imperfect control, and the heart bounds with pulsations, rapid, interrupted, and irregular.

Take two men of similar constitutional powers and liabilities; abstract from one of them twenty ounces of blood; subject them both to the poison of typhus fever. Which of the two is most likely to imbibe the disease, and which to escape the contagion?—and why? Because in the man from whom the pabulum has been drawn we find want of power to withstand disease.

Practically based on the same principle is the good old-fashioned notion that a man should not encounter fever or other contagious disease on an empty stomach. The more he is reduced the greater his liability.

Is not the constitution a surer mark for every description of disease—apoplexy itself, perhaps, and inflammation, not excluded—under a state of nervous system weakened by depletion? Undoubtedly it is. Two persons undergo a painful surgical operation: one loses twenty ounces of blood, the other five ounces only. Which is the more probable subject of subsequent inflammation? Unhesitatingly we may reply, the former. Where do we find the more serious and more frequent attacks of puerperal fever and inflammation of the uterus? In those women whose confinements have been attended with the greater amount of hemorrhage, who are reduced and rendered prostrate by loss of blood. The patient who has lost blood is more liable to inflammation than another, because, in the unhealthy condition of his nervous system, he is susceptible of irritation that a tonic condition of this system would throw off; and let it be remembered that it comes upon us with a reduced circulation and exhausted powers.

Dr. Gooch, Dr. Marshall Hall, and Mr. Travers have written excellently on these subjects. It is to be lamented that such works should ever be laid aside before they have been thoroughly studied, or until the precepts therein inculcated have sunk deeply into the mind, and become "familiar as household words."

It is not an unusual practice, that of administering a large dose of calomel and other form of depressing aperient immediately on the occurrence of a large accident, such as compound fracture or severe injury to the head.

It would be difficult to explain the *rationale* of this practice, infinitely more honoured in the breach than in the observance. What end is answered by a drastic purgative but weakness, exasperating the injury already sufficiently great to call into requisition all the energies of reparation. If it be intended as a protection against future inflammation, erroneous indeed is the intention, and inoperative the means, except for mischief.

Analogous to this principle—which may be compared in military matters to the futile endeavour to destroy a besieging army by repeated sorties of detachments from a weakened garrison, the concentrated force of which is required for the final struggle—is the ancient and partly obsolete practice of preparing patients for operation by gradual depletion; or the reducing process adopted after the operation, with the mistaken purpose of preventing inflammation. All this is done in direct violation of a law which prescribes a tonic condition of the nervous system, as the most favourable for the performance of all large surgical operations.

It may be easily comprehended that a man of indulgent habits and prone to obesity may undergo a process of moderate reduction of his weight by regulated diet, reasonable purgation, and active exercise. But such means tend to tighten, instead of to relax, the cords of his nervous system. This is not the nature nor the principle of the reduction alluded to. These agents promote health, increase the strength, and give tone to the actions of the heart, and to the general functions of the body. The term reduction may apply to his weight and to the heats of his pulse, which latter is reduced from a standard of false excitement to that of tonic health, and in the same degree it presents a condition of his system most tolerant of injury to its integrity.

The frequent failure of operations of expediency does not militate against this principle, healthy as the system may be at the time of their performance. In the last work of a deservedly eminent surgeon, the principle of such depletive preparation in cases of operative surgery, which has in view the depression or reduction of the individual; as likewise that which reduces the patient, after the operation, for the purpose of preventing inflammation, has been most properly denounced—late though the just denunciation reach us.

"Do we take sufficient cognizance," said an eminent surgeon, who had himself recently been the subject of a serious accident, "with our

purgations and our bleedings, of the shock our nervous system has sustained?" "I think not," was the reply; "and it may be well that this accident has happened to you rather than to another."

And so it is: we adopt the practice of bleeding without reflecting on its consequences, because we have observed that it may afford temporary relief, even in neuralgic affections, and without taking note of the palpable fact, that undue fulness of the circulation may be concurrent with a morbid state of the nervous system.

The comparative mortality in the circle of general practice is a bad criterion of the efficacy of this or that principle. It is only in large hospitals where the experiment can be fully tested. No doubt more blood may be taken with impunity in the country than in the metropolis, but the principle holds the same.

It is a curious fact, that many eminent members of our profession eschew the lancet altogether. They declare that they never bleed; that bleeding is gone out of fashion; and a most unprofitable fashion it is. An invaluable agent occasionally in the hands of the judicious, but an instrument of much evil when indiscriminately resorted to.

To illustrate the foregoing remarks I will describe two cases. The first of these belongs to a class of most frequent occurrence, in which depletives, general and local—for they are, of course, identical in their influence—impair the reparatory powers of the constitution, protracting the progress of the disease towards recovery, both positively, by the ill-timed administration of local agents, and negatively, by the denial of such general means as tend to promote the health through increased vigour given to the circulation.

A lady, consequent on her confinement, has pain and hardness in the breast. On inquiry it will be found that she has had what is called a hard time. She was in labour many hours, and lost more than the usual quantity of blood. Her skin is clammy; her pulse is large but soft and compressible; her appetite doubtful and uncertain, having, probably, a tendency to relaxed bowels.

Now, there are three modes of attacking this local plethora:—1, by local depletion; 2, by promoting action elsewhere, and raising the standard of the general health; and 3, by the combination of the two former.

The local reduction is attempted by leeches, of which about eight may be applied, and from which such temporary relief from pain follows as to lead to a repetition of the remedy. But the cause of the local plethora, which is advancing towards abscess, is not affected: it remains as before; and the suppurative action, slightly arrested for the time, rallies and reforms, and abscess generally follows in the end. The local application has given relief from pain, and pain only. The constitutional powers are reduced by loss of blood, occasioned directly by the leeches, and indirectly, by an aperient, which has been ordered as their usual concomitant. The benefit derived by the local depletion must also be

benefit derived employed early.

They are worse than useless in abscess, of doubtful good in established suppurative action, and pertinent only in the first stage of inflammation: for when applied in the second stage, they often tend, by their local irritation, to promote the completion of the process by the formation of matter. Nor is it an unreasonable inference that, in virtue of the reducing influence of the leeches on the circulation, the abscess, which almost certainly follows, will be larger in size than if it had formed without the aid of surgical art, and will be much more protracted in its progress.

The second form of treatment consists in raising the standard of the general health; and

this would appear at once the more rational, as it is unquestionably the more successful, mode of contending against the impending evil.

The constitution is primarily at fault, not the breast; and to attack the breast for a fault of the constitution is, to use the language of Mr. Abernethy, "to minister to a symptom." Tonic medicine, porter, good diet, in fact, tonic treatment, to meet an atonic system. No purgative, no local depletion, no handling of the breast, which should for the time be entirely forgotten. Compound tincture of bark with mineral acid, meat diet, the breast supported without pressure by the local application of a thick fold of wadding, will determine in the course of a day or two what Nature intends. The appetite will be increased, sleep promoted, and health improved. If the local disease be engaged in the first stage, or that of inflammation, suppurative action will be finally arrested, and the thickened mass will be gradually absorbed. If in the second stage of suppurative action, the tonic treatment will answer two important indications, viz., the diseased actions will be limited in degree; the formation of matter, though it may not be arrested, will both be reduced in quantity and, what is of little less importance, the crisis will be accelerated. All that part of the swollen gland in which suppurative action is thoroughly established will be pushed on to the completion of abscess; all the remainder will be absorbed.

The advantages, then, are, that the period of suffering is abridged, the disease itself is limited by tonic treatment, and the health is improved. We force on a diseased process in a healthy, instead of prolonging it in an unhealthy, state of constitution, and in so doing we accomplish the great end of treatment—the early restoration of the patient to her family circle.

In like manner, and acting on the same principle, in those cases of chronic enlargement of the glands of the groin following gonorrhoea or chronic venereal sores, in which there is not constitutional power sufficient to mature the disease to its crisis, bark will bring on this crisis in the course of a few days, and either the tumid mass is dissipated, or the crisis is perfected by the formation of a small abscess.

With respect to the third mode of treatment, which consists in a combination of the local and general, it is only applicable in the first stage of inflammatory thickening. It is a great mistake to suppose that local depletion and tonic medicine are subversive of each other's influence. It is called "blowing hot and cold." It would be difficult to devise a better principle for restoring a disturbed balance of the system so apparent in these cases, than that of blowing hot when it is cold, and cold when it is hot; and this, in fact, is the application, to give force to the system weakened by illness, and abstract blood where there exists local congestion. But the abstraction of blood should be adopted with caution, avoiding alike the irritation of the local agent, whether leeches or cupping-glasses, and the reaction of the constitutional powers consequent on loss of blood.

The other form of cure is an example in which the nervous system sinks under the effects either of depletion or of local injury, for the one was as frequent a cause of collapse as the other. I quote it because it speaks plainly, although it labours under these disadvantages, that it is of a negative rather than positive kind, and has been before alluded to elsewhere. But I select it in illustration of another important principle to be ever kept in view—the performance of surgical operations, viz., that operations of expediency are dangerous by their sudden shock to the nervous system, which is unprepared for the attack. In such a condition of the system all operations are dangerous, and the larger ones often fatal. Operations cannot be done on the human body with impunity unless the nervous system takes necessity, acknowledging, as it were, the presence of an evil to be got rid of. A wound into a healthy knee-joint is generally fatal to the structure of the joint, whereas we cut into a diseased knee-joint with impunity. The

same remark applies to the bladder and to other cavities of the body, whether mucous, serous, or synovial.

A medical man passed into the bladder of a patient, a young man of twenty-three, an elastic catheter (No. 8). In withdrawing the instrument, it broke in half, one portion remaining in the bladder. He walked to St. Bartholomew's Hospital, and I saw him. Would it have been safe to have cut into this man's bladder, under the circumstances of his case, without either pain or even uneasiness? I think not.

I saw him daily in good health, without suffering, passing water freely, with a good appetite for food, and sleeping soundly. Thus passed ten days.

On the eleventh he complained of pain in the bladder; he had passed a disturbed night, with frequent attempts at micturition; pressure on the bladder gave him uneasiness. On that day I removed the catheter by the lateral operation; about two ounces of blood were lost.

On the following morning, eighteen or twenty hours after the operation, he was attacked with severe pain extending all over the abdomen, great restiveness, headache, hot skin, and had a bounding pulse of 120. He was under the immediate charge of a very intelligent house-surgeon, and under the observation of dressers and students, many of whom were present on the occasion; and almost to a man, when I inquired of them the views they took of the condition of this patient, said he had inflammation of the bladder, or peritonæum, and recommending bleeding on a large scale. In the first place, there were not symptoms of inflammation; and, in the second, had inflammation followed, it would not have appeared under forty hours, at the earliest period. There were nervous symptoms resulting from the shock sustained to his constitution by the operation on a bladder hardly yet prepared to sustain it. A large dose of ammonia and opium sent him to sleep, and, on awaking after six hours, every vestige of danger or difficulty had subsided. In three weeks he was quite well, and at the expiration of the fifth week he married. Had this man been bled, I believe he would have had an attack of inflammation, or something worse.

This is a strongly-marked case. But allusion to strongly-marked cases is not requisite in enforcing the immense importance of this principle, which exhibits itself to daily observation in the occurrence of a train of small, but palpable, manifestations of such disturbance to the nervous system as can only be met by treatment expressly directed to that system, but which, apparent though they be to an observing eye, are, for the welfare of the sick, too often referred to the fault of the circulation, notwithstanding the repeated warnings we have from time to time received from the heads of our profession.

Grosvenor-street, Oct. 4.

CONTRIBUTION TOWARDS A MORE ACCURATE THEORY OF THE "TARTARUS BORAXATUS," AND ANNOUNCEMENT OF VARIOUS OTHER SALTS FORMED BY THE BORO-TARTARIUM ACID.

By GEORGE WILLIAM II. KRUG,

Doctor in Philosophy of the University of Jena, and Apothecary in the City of Campinas, Province of São Paulo, Brazil.

Previous to entering into detail, it is necessary to mention that there exist two essentially different formulæ for the preparation of tartarus boraxatus. The Parisian Codex directs it to be formed from the bitartrate of potassa with boric acid, while almost all the other Pharmacopœias and books of formularies, though differing as to the relative proportions, order the employment of bitartrate of potassa with biborate of soda. The original formula, given by Lefèvre, a physician of Ulm, directs one part of the biborate of soda to three of the bitartrate of potassa: these are those most generally employed. My remarks, therefore, have reference chiefly to the products

of these two formulæ, as representatives of the various specimens of tartarus boraxatus which occur.

In the actual state of science, with respect to tartarus boraxatus, there indubitably exist many deficiencies, and also errors, as may be at once presumed from the differing opinions of various chemical authorities concerning the nature and composition of this preparation; and, moreover, I believe that, up to the present, no one yet occupied himself in the investigation as to the existence of other salts, into whose composition entered jointly the boric and tartaric acids, whose results must necessarily be a great aid to the attainment of an exact knowledge of the tartarus boraxatus itself.

Very recently, the authority of Baron Liebig sanctioned the theory and formula of a so-called tartrate of potassa and boric acid, with the constitution noted in the subjoined diagram:—
(2—T×KO, BO₃).

The proposer of this theory, M. Duflos, apothecary in Breslau, attributes to the boric acid in this combination the part of a base, and insinuates that such tartrate of potassa and boric acid is a salt analogous to the tartar emetic, in which the boric acid represents the same part as the oxide of antimony in the latter salt. This very plausible idea appears to have induced Liebig to give the before-mentioned sanction. Duflos directs the salt to be formed from weights relatively representing one atom bitartrate of potassa, and one atom boric acid. The formula of the Parisian Codex for the preparation of tartarus boraxatus gives quantities which represent rather less than two atoms of the bitartrate with one of boric acid; this preparation is, therefore, by Duflos, stated to be a mixture of free bitartrate of potassa with his supposed tartrate of potassa and boric acid. Consistently with the foregoing, he supposes the tartarus boraxatus of the original formula (that of Lefèvre) to be a double salt, composed of one atom of the tartrate of soda and potassa (sal polychreston seignetti) with two atoms of the tartrate of potassa and boric acid, as in the accompanying diagram:—
(KO, NaO×2—T) and 2 (2—T×KO, BO₃).

There is, however, to be found in the memoir of M. Duflos a contradiction so great that it overwhelms his whole theory, and it is surprising that it should have escaped the penetration of the distinguished Liebig. It is, in brief, this:—Duflos says, that the neutral and soluble tartrates produce a precipitate of bitartrate of potassa in the solution of tartrate of potassa and boric acid. But in the tartarus boraxatus of the original formula he teaches the existence of a neutral tartrate (sodæ potassio-tartarus, P. L.), conjointly present without visible perturbation, with the supposed tartrate of potassa and boric acid, and says that this so-called double salt dissolves readily, and without any residuum, in a small quantity of water.

The present memoir will show that the entire theory is false and unfounded; that neither the tartarus boraxatus of the Codex, nor that of the original formula, are truly chemical combinations, but that they are neither more nor less than mixtures of bitartrate of potassa (in a more or less modified form) with two several chemical combinations of a highly interesting character, which contain a double acid composed of the boric and tartaric acids. To establish these facts, I undertook a series of experiments, whose description I shall give below, and shall follow these by a statement of the conclusions to be legitimately drawn from them.

EXPERIMENTS.

No. 1. Weights representing relatively one atom biborate of soda and one atom tartaric acid (C₄ H₄ O₅ and H₂ O) were dissolved together in the minimum quantity of boiling water necessary for solution. The liquid, whose reactions were neutral, was quickly filtered and set aside to cool. After the lapse of some time there was a separation of crystals from the solution, which, carefully purified, were found to be pure boric acid, being perfectly soluble in alcohol and

tinging its flame with the characteristic green. The liquid in which these crystals formed was repeatedly agitated with the strongest alcohol to extract any free boric acid which it might still contain. Treated in this manner, the liquid had the physical appearance of a syrup, and a neutral reaction. It was impossible to obtain crystals from it; when evaporated, there remained an anhydrous mass, gummiform, and highly hygroscopic. According to my views, one atom of boric acid was expelled from the borax by the influence of one atom of tartaric acid, while this last formed with the remainder a new salt to which I wish to give the name of boro-tartrate of soda. The formula of this salt appears from the following diagram:—

In further confirmation of my opinion I performed the experiment No. 2. Direct production of boro-tartrate of Soda. The relative weights of one atom of borax, of one atom of carbonate of soda, and of two atoms of tartaric acid were dissolved together in water. The solution was rapid and complete, with liberation of carbonic-acid gas. After filtration no trace of boric acid separated, neither did the liquid when concentrated and treated with alcohol yield any portion of such acid. The solution had a neutral reaction, and formed on evaporation a gummiform mass in all respects identical with that produced during the first experiment. The theory of this preparation is

and this opinion is still further supported by

No. 3. Relative weights of equal numbers of atoms of borax and bitartrate of potassa were dissolved in boiling water. The solution was quickly effected, and some time after the filtration nothing was separated, save a little tartrate of lime (an impurity generally present in cream of tartar). The solution, filtered anew, had a perfectly neutral reaction; showed no disposition to crystallize, and, when evaporated, yielded an anhydrous mass, hygroscopic and gummiform, which, treated with strong alcohol, afforded no traces either of boric or tartaric acid. This diagram represents the theory and formula of this combination:—

which I consider to be a double neutral salt, the boro-tartrate of potassa and soda.

No. 4. Results entirely analogous were obtained by the joint solution of equal atoms of biborate of soda and of bitartrate of ammonia. To the salt produced, the annexed formula is applicable:— $[\text{NaO}, \text{N}_2 \text{H}_8 \text{O} \times 2(\text{BO}_3 - \text{T})]$. The boro-tartrate of soda and ammonia is also anhydrous, gelatinous, and hygroscopic.

No. 5. The relative weights of one atom of biborate of soda, of one atom carbonate of lime, and of two atoms tartaric acid were triturated with water in a mortar. The reaction was tardy in developing itself, the carbonic-acid gas being disengaged with much difficulty; on this account a very gentle heat was applied, when immediately the fluid became of a gluey consistence, having every appearance of decomposition. It appears to me, therefore, that the double salt thus represented $[\text{NaO}, \text{CaO} \times 2(\text{BO}_3 - \text{T})]$, allowing it to exist, is excessively unstable in the attractions by which its components are united.

No. 6. Equal atoms of carbonate of lime and of boric and tartaric acids were triturated with water in a mortar: there resulted a perfect and neutral solution, having the characteristic taste of the soluble salts of lime. After, however, the lapse of a few hours, the fluid became spontaneously thick as glue, with all the signs of decomposition. A small portion, however, was still in a state which admitted its passage through the filter, the reaction was still neutral, and the taste as above. Apparently then, there exists this salt $(\text{CaO} \times \text{BO}_3 - \text{T})$, but this boro-tartrate of lime is also a very unstable compound.

No. 7. Weights representing four atoms of borax with one of the carbonate of magnesia of

the shops [$\text{MgO} + \text{H}_2\text{O} + 3(\text{MgO} + \text{CO}_2)$], and eight atoms of tartaric acid, were dissolved together in water. The solution was instantly effervescent, with liberation of carbonic-acid gas. The fluid was clear and neutral, and showed no decomposition. Crystals formed on it; but there remained a substance anhydrous, gelatinous, and opaque, represented by the following formula:—

[$\text{NaO}, \text{H}^2\text{O} + 2(\text{BO}_3, \text{T})$]. The borate of magnesia. Native weights of one atom of borate of magnesia, of four ditto of four ditto tartaric acid, were rubbed together in cold water in a mortar. The reaction was rapid and attended with considerable elevation of temperature, there resulting a perfectly neutral solution whose taste had a striking resemblance to that of sulphate of magnesia. No crystals were procurable, and on evaporation there remained an amorphous, anhydrous, gelatinous, and highly hygroscopic mass—a salt whose composition is thus represented:—($\text{MgO} + \text{BO}_3, \text{T}$).

No. 9. I mixed together the saturated solutions of two atoms of the borotartarate of soda, and of one atom sulphate of copper [$\text{CuO} + \text{SO}_3$]. The resulting clear liquid was placed in a long cylindrical phial, and upon it was carefully poured concentrated alcohol. The phial was then placed aside, and left untouched for the term of three weeks, at the close of which the alcohol was found to have attracted to itself nearly all the water of the solution. On decanting the fluid there was found at the bottom of the phial a crustiform mass of a clear blue colour, which at some points near its surface showed an almost trace of crystallization in small, round, button-like conglomerations. Within this blue mass there were discovered large and beautiful crystals of sulphate of soda. This blue salt was anhydrous, anhygroscopic, and unchangeable by exposure to the air; was slightly soluble in water, and the reaction was similar to that of the neutral salts of copper. This combination, therefore, consisted of soda, oxide of copper, and boro-tartaric acid. The diagram here given shows the theory of the formation of the new double salt.

$2(\text{NaO} + \text{BO}_3, \text{T}) + \text{CuO} + \text{SO}_3 = \text{NaO} + \text{SO}_3 + [\text{NaO} + \text{BO}_3, \text{T} + \text{CuO} + \text{CO}_3, \text{T}]$.

No. 10. Equal atoms of boro-tartarate of soda and sulphate of copper were mixed together in solution; immediately there fell a fine and abundant precipitate of a clear blue colour. The supernatant fluid had a bluish tint, evidencing a certain degree of solubility of the precipitate. The fluid contained sulphate of soda; the precipitate was borotartarate of copper ($\text{CuO} + \text{BO}_3, \text{T}$).

No. 11. Relative weights of one atom tartaric acid, and of two atoms of tartaric acid were dissolved together in boiling water. The solution was filtered and put aside. After the lapse of a little time the tartaric acid and boric acid were found separately crystallized, and were with the greatest ease separable by means of alcohol.

No. 12. The well-known acid reaction of the tartarus boraxatus renders very probable the existence of biboro-tartrates. With a view to obtain information on this head, I dissolved a quantity representing one atom of boro-tartarate of soda with the equivalent of two atoms of tartaric acid. The quantity of water required for the solution was very small, and this was quickly effected. The resulting fluid was limpid, and the reaction and taste were sensibly acid, and the latter very agreeable. By spontaneous evaporation there was procured a mass, scarcely hygroscopic, and showing a very confused cauliflower-like crystallization. When treated with alcohol neither boric nor tartaric acid was obtainable from it. For want of a sufficiently delicate apparatus I could not ascertain whether or no it was perfectly anhydrous; if it be, then it is represented thus— $\text{NaO} + 2(\text{BO}_3, \text{T})$; but the trace of crystallization which appeared

renders it highly probable that this salt contains water essential to its composition, and then the following formula is applicable:—

[$\text{NaO}, \text{H}^2\text{O} + 2(\text{BO}_3, \text{T})$].

I obtained results entirely analogous, from the conjoint solution of one atom of bitartrate of potassa with two atoms of boric acid: there being formed in this case the biboro-tartrate of potassa.

No. 13. Equal atoms of the boric and tartaric acids having been dissolved together in a little water, after a short time crystals of boric acid were deposited, the tartaric acid remaining in solution.

Having thus, as a preliminary measure, completed the above experiments, I proceeded to a more intimate investigation of the "tartarate of soda and boric acid" (so called by the proposer of the theory, Duflos), and of the tartarus boraxatus of the original formula, and so instituted the experiment.

No. 14. Equal atoms of bitartrate of potassa and of boric acid were digested together in water for some time. The solution proceeded slowly, but at length became complete, yielding an acid liquid from which fell a scanty precipitate of tartarate of lime. The solution was filtered, and evaporated to dryness; no signs of crystallization appeared during the process. The residuum was anhydrous acid, and very slightly hygroscopic. No free acid could be extracted from it by means of alcohol. Neutral soluble tartrates precipitated bitartrate of potassa from the solution of this mass. From these facts, this salt of Duflos ought to be considered as a double salt thus constituted [$(\text{KO} + 2(\text{BO}_3, \text{T}) + \text{KO} + 2\text{T})$]. Thus accounting for the materials $2(\text{KO} + 2\text{T}) + 2(\text{BO}_3)$ employed in the experiment. This double salt is composed of equal atoms of biboro-tartrate of potassa and of bitartrate of potassa without water. (According to the discoveries of Frey the anhydric bitartrate of potassa is = neutral tartrate of the same base. On this point, however, every one is at liberty to adopt his own view.) In what manner the neutral tartrates precipitate the bitartrate of potassa from the solution of this salt, we shall afterwards see.

No. 15. Relative weights of one atom boro-tartarate of soda and two atoms bitartrate of potassa (which corresponds approximately to one part borax and two parts cream of tartar in absolute weight, as the atomic weights of these two salts differ but a very little) were dissolved together in boiling water. The solution, after filtration, was evaporated to the consistence of a weak syrup, and then set aside for some days. A little tartrate of lime fell to the bottom, but no trace of bitartrate of potassa. When evaporated, there remained a gelatinous mass, anhydric and highly hygroscopic, from which nothing was extracted by digestion in alcohol. I consider this combination as thus constituted:— $[(\text{NaO} + 2(\text{BO}_3, \text{T}) + 2(\text{KO} + \text{T}))]$. There thus appears a notable relation between this salt and that of Duflos. Reducing the formula of both these combinations to the general type, and for this end substituting both K and Na by R, the formula of the salt of Duflos is [$(\text{RO} + 2(\text{BO}_3, \text{T})) + (\text{RO} + 2\text{T})$], and that of the other double salt [$(\text{RO} + 2(\text{BO}_3, \text{T})) + 2(\text{RO} + \text{T})$]. In the former salt there being only an atom RO less than in the latter.

But what is still more singular is, that both these salts are mutually and at will transformable: to wit, mixing one atom of the first salt in solution with another solution of two atoms of tartrate of potassa, we regenerate one atom of bitartrate of potassa, which precipitates itself, whilst one atom of the second salt will be found in the solution. On the other hand, mixing the solution of one atom of the second salt with that of two atoms of tartaric acid, there also falls a precipitate of cream of tartar; but now there remains in solution an atom of the first salt. These two salts may, however, exist together in solution without any precipitation. Another singular peculiarity is, that there exists in the second salt tartrate of potassa, united with another acid salt without decomposition.

No. 16. Weights representing respectively one atom of boro-tartarate of soda and three of bitartrate of potassa (corresponding nearly to one part of the former and three of the latter) were dissolved together in boiling water; the solution was then evaporated to the consistence of a weak syrup, and remained untouched for one month. During this time a considerable precipitation took place, the precipitate exceeding in weight the fourth part of the cream of tartar employed, and consisted of tartrate of lime, with bitartrate of potassa. This occurrence affirms still more my opinion as to the constitution of tartarus boraxatus; but, as the partisans of the theory of Duflos may insinuate that the tartrate of lime alone, which is always found as an impurity accompanying cream of tartar, may be the cause of this decomposition, determining the formation and separation of a double salt, soluble with difficulty, and composed of tartrate of lime and bitartrate of potassa, it becomes necessary to disprove anticipatively such views, and for this purpose I made the following experiment:—

No. 17. Duflos gives the formula of the tartarus boraxatus of the original prescription— $[(\text{KO}, \text{NaO} + 2\text{T}) + 2(\text{KO} + \text{BO}_3, 2\text{T})]$; this, reduced to the general type, both K and Na being replaced by R, becomes [$(\text{RO}, \text{RO} + 2\text{T}) + 2(\text{RO} + \text{BO}_3, 2\text{T})$]. The first member of such combination I produced by the solution of one atom of salt of seignette ($\text{KO}, \text{NaO} + 2\text{T}$) in a little water. The other member of the combination was produced by the dissolution of one atom of borax, of one atom of carbonate of soda, and of four atoms tartaric acid, together, in a little water. It is evident that I took all possible means of rendering difficult the production of bitartrate of potassa, all the ingredients used in the experiment containing only one atom of potassa. All the substances employed were quite free from lime. Nevertheless, on mixing the two limpid solutions, there fell in a short time a proportional precipitate of bitartrate of potassa (approximately corresponding to one atom). I view this result as a definitive affirmation of my opinion, because, subtracting from the formula of Duflos one atom of bitartrate of potassa, there remain exactly the elements of my formula:—

$[(\text{NaO} + 2(\text{BO}_3, \text{T})) + 2(\text{KO} + \text{T})]$.

As to the assertion that the concentrated solution of tartarus boraxatus of the original formula of Lefèvre, perfectly free from lime, and which, previous to solution, was evaporated thoroughly to dryness, does not, even after the lapse of years, offer any trace of a precipitate, it is a point cannot yet decide from individual experience. But, even supposing this to be the fact, I rather believe that that one superfluous atom of bitartrate of potassa undergoes a modification by the excessive heat employed in the last stage of evaporation, which modification is the cause of its persistent solubility. It is useful here to recall to memory the discoveries of Frey on the tartrates. In this very case it may be that the foresaid superfluous atom of bitartrate of potassa becomes transformed into an atom of tartrate of potassa, which salt is very soluble, and differs from cream of tartar only in one atom of water which it contains less than cream of tartar.

CONCLUSIONS DEDUCED FROM THE FOREGOING STATEMENT.

I. There exists a peculiar double acid, composed of boric and tartaric acids; but it only exists in combination with oxides in the form of salts, of which, at least, the greater number are anhydric. This rests on almost all my experiments; principally, however, it is proved by the experiment No. 8. No. 13 shows that this acid cannot exist in a free state. This double acid is represented by the diagram, (BO_3, T); its neutral salts by this, ($\text{RO} + \text{BO}_3, \text{T}$); its neutral double salts by this diagram, [$(\text{RO} + \text{BO}_3, \text{T}) + (\text{RO} + \text{BO}_3, \text{T})$]; and its acid salts thus, ($\text{RO} + (\text{BO}_3, \text{T})$); (but it may be that these acids also contain basic water, and in this the following diagram will more correctly represent them:— $\text{RO}, \text{H}^2\text{O} + 2(\text{BO}_3, \text{T})$).

II. The affinities of this double acid appear very unequal in the several compounds it forms.

In experiments Nos. 8, 14, and 15, if appears to possess strong affinities, capable of overcoming great difficulties; but, as to the salts of lime, they appeared to be, on the contrary, extremely weak.

III. A compound of this acid which corresponds to tartar emetic does not exist.

IV. Neither is there any analogy between the salt called by Duflos "tartrate of potassa and boracic acid," and tartar emetic. The true formula of this salt of Duflos is $[(KO + 2(BO_3, T)) + KO + 2T]$.

V. The tartarus boraxatus of the Parisian Codex is a mixture of this salt of Duflos with cream of tartar (which may be more or less transformed into tartrelate of potassa).

VI. The tartarus boraxatus of the original prescription is also a mixture of cream of tartar (which may be more or less modified into a tartrelate of potassa) with a double salt thus constituted, $[(NaO + 2(BO_3, T)) + 2(KO + T)]$; and this, in my opinion, is the true tartarus boraxatus.

Finally, I think it not superfluous to recommend to chemists who can dispose of greater facilities than myself, to study more closely this double acid, and to extend their investigations to more of its combinations with the several oxides.

It is only by the repetition and further extension of the experiments that a just and exact idea can be formed of the nature and constitution of these interesting compounds, in which chemical affinity appears to have nearly reached its extreme limits, and displays relations of a very singular, and at times anomalous, nature.

THE PHYSIOGNOMY OF DISEASES OR SEMEIOTICS IN THEIR ASSIMILATIVE CHARACTERS.

By GEORGE CORFEE (Author of "A Popular Treatise on the Kidney," &c.), of the Middlesex Hospital.
(Illustrated by Portraits of Cases.)

(Continued from p. 639.)

The subjoined table will give my readers, at one glance, the various poisons that have been taken, mostly for a suicidal purpose, together with the attempts to destroy life by other means, by each sex, during the space of fifteen years. The number, during that period, that have been relieved, and sent away as out-patients, has, also, been considerable; but these casual cases are not included, but only those individuals in which the dose taken, and the severity of the symptoms, warranted us in admitting them as patients into the medical or surgical wards.

drug six hours before admission, and he was, to all appearances, dead when brought into the room; the pulse was intermittent, the respirations convulsively performed, not more than two in a minute; the face and pupils contracted; and the extremities cold. After the administration of a siphon-pump, electro-galvanism, and other means, our powerful machines, were separately employed. In three hours he roused up suddenly, as if from an almost lifeless state to one of excitement and anger, calling us "brutes," "savages," and "beasts," for trying our experiments upon him. He left the hospital quite recovered afterwards, but eventually killed himself by a self-administered dose of arsenic.

The second case (apoplexia renalis or ischuria renalis), in a female, was admitted labouring under the very same symptoms. Perfect insensibility, which had existed ten hours prior to her entrance into the hospital; contracted pupils; and convulsive, slow breathing. She died in four hours and a half after her being seen by us. There was strong presumptive evidence that she, also, had taken poison, as a three-ounce phial, containing laudanum, was seen the preceding day, and could not now be found. However, it was proved on the inquest that the laudanum had been used the preceding night by her niece, as a liniment over the loins for severe pain experienced there, and that she never had been allowed to touch it as an internal medicine. The examination of the body, after a patient investigation, fully proved that the cause of death arose from advanced "morbus Brightii." The kidneys presented the usual ravages of that disease; the bladder was perfectly empty, the size of a walnut; and the medical gentleman who had been in attendance upon her for some months stated that the urine, when any could be obtained, was always highly albuminous, and that anasarca had shown itself some weeks prior to her fatal attack. (a)

I may here remark, too, that the shocks of electricity produced a faltering of the pulse and a diminution of the vital powers in this instance; whilst, in the first case, they evidently acted most wonderfully and powerfully upon the brain and general circulation, rousing the respiratory system to a surprising activity in the course of one hour after the administration of this therapeutic agent.

On another occasion a man was brought into the hospital by some strangers, having been found in a stable on the horse's bed. He was perfectly senseless. Countenance bloated and dingy, pupils contracted, and breathing laborious; pulse full and jerking. It was a difficult point to decide whether these symptoms were the result of a kick from the horse, intoxication, apoplexy, serous effusion into the ventricles, or poison from some narcotic drug. As there appeared a slight tendency to convulsions over the features of the face, it might have been the sequel of an epileptic fit; however, none of these surmises proved correct, for, whilst the servants were busy in undressing him, his feet were observed to be oedematous. A catheter was passed, and a few drops of urine were obtained, which was highly albuminous on the addition of nitric acid. The case now was made clear to our minds. It was poison from urea, the result of ischuria renalis. His head was shaved, blood was taken from his temples by leeches, he was made to swallow a purgative draught, and a turpentine enema was administered. He rallied out of this comatose condition, and then informed us that he had suffered for a long time with aching pain in his loins, occasional giddiness, and dimness of sight; that his urine had been

(a) I am not sure that our Professor of Chemistry did not obtain some beautiful crystals of nitrate of urea, from the fluid which we collected for his analysis, in the ventricles of the brain in this female. But I have seen this salt procured, on other occasions, in considerable quantity from the same fluid, in fatal cases of cerebral effusion, consequent upon the disease termed morbus Brightii.

APOPLEXIA RENALIS,

from renal degeneration, is a disease that has been so frequently mistaken for sanguineous cerebral effusion on the one hand, and for poison by laudanum on the other, that we may group the affection with cerebral asphyxia, for the purpose of showing the assimilation of features of the three diseases. In order to effect this, I think I cannot do better than present to the reader an abstract of two striking illustrations of the above affections, namely, narcotism by laudanum, and insensibility from the presence of urea in the brain, which were published by me soon after the period of their occurrence. The one (of laudanum), a male patient, had taken an ounce and half of this

scanty of late; and that "his head became so bad" that he fell down whilst cleaning the horses, and was unconscious of all that had passed since. He was cupped to the loins, and had repeated doses of our Pil. Elaterii co., with warm baths, and ultimately recovered, though the urine remained slightly albuminous. Some such such insidious and difficult cases could be enumerated, which have been mistaken by the practitioner before he has sent the patients here; for apoplexy and active depletion has been resorted to under that impression; whereas the rapid evacuation of the bowels, by powerful doses of elaterium and moderate leeching to the temples and blisters to the vertex of the head, have proved the most successful plan of treatment in these wards. Some cases have terminated fatally, and crystals of nitrate of urea have been obtained by the Professor of Chemistry from the fluid in the ventricles of the brain, as I have already remarked. There is no stage of albuminous disease of the kidney at which this suppression of urine, and subsequent coma, may not creep on. A large secretion of pale, light urine, of a low specific gravity, with little or no albumen, may as suddenly become suppressed, as a small quantity of this secretion which is muddy and like small beer, frothy, and loaded with albumen. The main test is the high specific gravity, as this will always inform us whether a due proportion of solid material is eliminated by the kidneys. The presence of albumen is a secondary consideration.

In connection with the foregoing remarks it should be observed, that serious disturbance takes place in the brain from another form of renal disorder, totally opposed to the one just adverted to. There is no disease in these organs, but they are rather acting as the "medicatrix nature," in striving to separate noxious principles from the system; and this they do in the form of lithic acid crystals. The disorder is usually set up in persons who have lived well upon animal food; who are bony, muscular, and well-formed individuals.

A man has just left the medical wards under the care of Dr. Hawkins who was of this description; he worked at the City barges as "hopper," and, not being such a tippler as most of this class, he ate heartily of animal food several times a day. He came to us labouring under "epileptic fits." He was a most athletic fellow, and, had he not been attacked with a fit in the hospital, one would have been disposed to doubt the statement he made of his previous seizures. He had constant pain over the right hemisphere, with some vertigo, tinnitus aurium, and slight deafness. Various plans of treatment were tried without avail; when at length, whilst under the influence of a diuretic, judiciously administered for the relief of his cerebral disturbance, he continued to pass every day, for a week or so, upwards of half a teaspoonful of red sand. His head symptoms rapidly disappeared, and he left the hospital perfectly convalescent.

The following comparative analysis of the elements of the urea, bile, sugar, and lithic acid may not be uninteresting to the reader:—

	Urea.	Bile.	Sugar.	Lithic acid.
Hydrogen	6.66	8.30	6.66	2.85
Carbon ..	19.99	58.46	39.99	34.28
Oxygen ..	28.06	22.61	53.33	23.85
Nitrogen	46.6	3.70	—	40.00
	100.00	100.00	100.00	100.00 (a)

COMA, OR TEMPORARY LOSS OF CONSCIOUSNESS FROM BILE, WORMS, &c., OR OTHER IRRITANTS.

Here, indeed, a wide field for observation is presented in this hospital, and fresh opportunities of viewing the chameleon colours of these changeable appearances are occurring daily.

In private practice, also, I doubt not that a very large number of disorders are constantly occurring, the symptoms of which are termed "apoplectic," "tendency to apoplexy," &c. &c.,

(a) "Dr. Prout on Urinary Diseases."

but which, in truth, may be called "biliary congestion," "hepatic engorgement," "pent-up or morbid cystic bile." I will, however, proceed to mention what I mean by these terms, and, in doing so, I may add that I now write, unfortunately, from some little personal experience of former days. An individual presents himself to your notice, describing his symptoms. He is a robust, well formed man, from thirty to fifty; inclined, perhaps, to corpulency, and may be he is "pansu," or, as the pauper females term it, "high stomached." He is fond of living freely upon animal food and beer, &c., and follows a somewhat sedentary life. He relates that he is occasionally attacked with pain over the forehead, to such a degree that he becomes quite muddled and unfit for work, or unable to exert himself either mentally or bodily, in his daily calling. There is, from time to time, tinnitus aurium and vertigo; he gets rather deaf in one or both ears; his sleep is either more heavy and prolonged than usual, or it is attended with horrid and disagreeable dreams, and he is more restless and feverish than he is wont to be. He has but little appetite, his knees totter under him as he walks, his heart intermits, he is occasionally short in his breath, and he thinks himself weak and out of sorts; but does not know where he is ill, as he suffers little or no pain. Now, these ailments are the forerunners or shadowings forth of a more serious train of symptoms, which may, and do often, follow if active measures are not adopted for their mitigation. The patient goes on to describe a numbness felt down one arm and leg, an odd sensation in the face of the same side; his former symptoms continue, and he becomes uneasy and seeks for relief. When you see him enter the hospital admission-room, you observe an awkwardness of gait and tottering or dragging of one leg, an expressionless countenance, and a dull, heavy eye. He is evidently very low spirited, perhaps bursting into tears before he has told half his sad tale of suffering. Well, such cases formerly would have been called, and still are called by a very large class of practitioners, "apoplexy," and they are not considered safe, nor is it deemed legitimate practice, unless the arm is instantly laid bare, and the lancet made to let out twenty or thirty ounces of blood, with subsequent cupping or leeching in an unsparing manner to the head, &c. Whereas the admirable practice adopted in the medical wards of this hospital by Dr. Seth Thompson has taught me, by the extraordinary and gratifying results, that this practice is both useless and prejudicial.

As soon as the patient is in bed, a full dose of calomel and colocyath, such as five grains of the former and ten grains of the latter, is administered, followed up in four hours by a large cathartic draught; his head is shaved, and, if there is much heat about the forehead, eight or ten ounces of blood may be taken away by cupping behind the ears. But this is by no means an ordinary part of the treatment. In the course of the following morning the nurse shows us a copious evacuation, dark as the darkest mahogany or chocolate, fetid, abominably so, and containing but little fecal matter. This is cystic bile—bile that has been "laid up" in the gall-bladder—that has become inspissated, heavy, and morbid, and could not find its way into the common duct, owing to the gorged state of the hepatic biliary system on the one hand, and to the congested mucous surface of the duodenum and stomach on the other. This bile is, therefore, a noxious accumulation, a morbid product, and acts as a poison upon the nervous and vascular system, just in the same way and in somewhat a similar manner to the poison of urea when it circulates in the blood, and is not sent forth by the kidneys. The dose is again and again repeated, perhaps for five, seven, or ten times, and at length pure healthy bile passes away, without taint, of a canary colour, and emitting a faint odour very analogous to the smell of the narcissus, or daffodil flower. The head becomes clear; the intellects brighten up; the patient is lively, active, and in good spirits; the

sleep is tranquil, refreshing, and moderate; the appetite becomes keen; and he walks across the ward with a firm, steady, and equal pace. But, although this manifest improvement has taken place since he has got rid of the "pent-up poison" that lurked in his system, yet does there still remain a slight weakness of the arm and leg. This excellent practice has been attended with singular benefit. A blister is now laid over the whole length of the longitudinal sinus, and the discharge is kept up from its surface by means of the savine ointment, whilst the purgative treatment alluded to is still persevered in from time to time. Thus have I seen cases, but especially during the last season, become perfectly convalescent, and leave the hospital without the slightest appearance of hemiplegia, and without having undergone any depletion.

The following is an instance of many such cases:—A female, about forty-five, entered an hotel in Bond-street, as charwoman, between six and seven o'clock in the morning (in March), and soon afterwards became faint, sat down in a chair, when the "boots" went and called up the master, who came down, and, finding her speechless and unable to walk on one leg, instantly ordered a cab, placed her in it, and came himself to the hospital with the patient. I saw her immediately on her admission, and, finding that she was of a spare habit and not a free liver, I was resolved to use no active depletion, but to counteract unloading her liver by calomel and colocyath, in no measured doses. Of course the master knew little of her habits, as she was merely an occasional scourer in his kitchen, &c., only that she was not addicted to drink, as he informed us. I believe it would astonish many practitioners, had they witnessed the beginning, progress, and gratifying termination of this case, under the judicious, bold, and decisive treatment of her physician, Dr. S. Thompson. After the evacuation of large quantities of dark bile, of the most fetid nature, penetrating in offensiveness of smell to such a degree that the moment a person entered the ward (thirty feet by eighteen feet) he might detect its effluvia; and after the free discharge of a blister applied over the whole vertex of the head, and when pure, pale, rhubarb-coloured bile began to flow, this patient not only regained the full use of her speech and faculties, but she got up, dressed, and fed herself—in short, walked about the wards and hospital garden, and left the institution as perfectly free from those symptoms, for which she entered it, as though she had never been the subject of such an alarming attack.

But I need not pursue the subject, although many, very many, such instances could be adduced, on the male as well as on the female side of the building, whose cases are recorded by the clinical clerks in their reports of the physicians' patients.

I have often had occasion to notice that, where a train of nervous symptoms arises from other causes than that of cerebral disease or lesion, the symptoms are by no means defined regular, or consistent.

The injury offered to the brain by a blow, bruise, or effusion—as in compression, sanguineous apoplexy, scrofulous disease, or tumour of the cerebral substance—often times presents a consistent train of nervous symptoms. But where the brain is the mere sufferer, and not the *fons et origo* of the train of symptoms presented to our notice, the nervous system is more indefinitely attacked, and the evidences of such an attack are equally incongruous. For example, here is an instance of cerebral disturbance just related, which would lead a discriminating pathologist to conclude that the woman was suffering from effusion into the crura cerebri, pons varolii, or cerebellum; she was speechless, and that, too, for several days. If it had so proved, death would almost have inevitably followed. But then there is hemiplegia, which is not the ordinary attendant of a sanguineous clot in this portion of the brain. Her speech returns perfectly before she obtains the full power of her limbs. This undoubtedly is the

FOREIGN PRACTICE.

WICK, Esq., Surgeon to the Western German Dispensary,
Paris, and formerly Externe to the Veneral Hospital,
Paris, &c.

ON A NEW OPERATION FOR THE REMOVAL OF
INGROWING NAIL. BY M. LONG, SURGEON TO
THE HÔPITAL CIVIL DE TOULON.

The operation for ingrowing nail, although simple, has attracted the attention of many distinguished surgeons. Among the numerous proceedings mentioned by authors, some have the defect of being palliative; others that of being either too long or too painful. The operation of M. Long possesses advantages, which has induced us to lay it before our readers.

The author, reflecting on the connections of the nail with the surrounding tissues, conceived the idea of removing it by its root with a common spatula. The numerous trials which he and his pupils made on the dead subject soon confirmed his opinion, and he was able to tear away the twenty nails in the short space of five minutes. It may be necessary to mention that the nails of some bodies are liable to tear; this is also the case if the nail has been softened by topical applications.

The operation is easily and quickly performed, and but slightly painful; it needs no preparation, and all that is required is an ordinary spatula. The patient is seated in a chair, with his foot resting on the operator's knee; the surgeon then takes the flat end of the spatula in his right hand, and, having placed his thumb on the concave, and the index and middle fingers on the convex surface, the other fingers being disengaged, proceeds slowly to separate the skin covering the root of the nail. When arrived at the post-mortem border, he suddenly elevates the flat end of the spatula, so that the instrument forms an acute angle with the diseased toe, and thus places its other end beneath the nail, which still adheres at the sides and centre. By then passing the spatula between the nail and the soft parts the evil is easily accomplished.

Such is the proceeding adopted by M. Long, and the results have always been successful. Among the patients operated on by this skillful surgeon we may mention one—a custom-house officer, who had on the right great toe an ingrowing nail, the sides of which were deeply imbedded in the flesh to the extent of about a centimètre (39-100ths, or rather more than two-fifths of an English inch). The evulsion of the nail was accomplished without pain, and without the slightest hemorrhage; the next day the patient returned to his occupation, and in fifteen days he observed a new nail make its appearance. We have ourselves performed this operation on a man, lying in the ward for the wounded, at the Toulon Hospital. This patient, a working mason, had received a violent contusion on the left great toe; there was traumatic onychia, and the nail was growing into the flesh. We effected the evulsion of the nail by M. Long's method: the patient left his bed on the fourth day, and on the twentieth he quitted the hospital, the new nail beginning to make its appearance.

In conclusion, we may state that the operation of M. Long appears applicable to all cases of disease of the nail in which evulsion is necessary; and we may add that its principal advantages are—1. In effecting a complete and definite cure; 2. In sparing the patient considerable suffering; 3. In causing no loss of blood; 4. In always allowing the tissues to reproduce a new nail, which has been the case in every instance where the operation has been performed by this method—*Gazette Medicale de Montpellier, L'Abeille Medicale*.

REMARKABLE DISEASE OF THE KIDNEY.

Communicated by H. NORRIS, Esq., F.R.C.S., South
Petherton.

Thyrza Hutchins, a child two years and ten

reverse in those instances of cerebral lesion where the patient is deprived of speech: the injury offered to the ninth pair of nerves, in apoplexy of the medulla oblongata, is scarcely ever so fully repaired as to enable the individual to articulate with clearness and freedom, although he may be able to walk about with firmness and vigour.

These observations will be found strictly correct, not only under the head of those hepatoneurotic diseases (disorders, should I not call them?) which I have been endeavouring to elucidate, but also under another fruitful source of hemiplegia, which is by no means rare in the practice of the medical wards of this hospital: I allude to the presence of worms in the intestinal canal. The following instance will explain my meaning, I hope, more fully:—A tall, robust countryman, from Berkshire, was admitted, under Dr. M. Crawford, into the hospital last year, with the following malady: His countenance was healthy, but his features were void of expression, there was a dulness of physiognomy; he complained of partial loss of sight of the left eye; the iris was natural and active. He had also, a numbness extending down the right arm and leg, and over the left side of the face. He suffered from occasional giddiness, so that he was oftentimes afraid to trust himself to walk alone even across the ward. The numbness down the leg was occasionally so severe that he could not walk even from his own bed to that of his neighbouring patient. His appetite and his spirits were tolerably good, and with the exception of a former attack of rheumatism, which had left sufficient traces of endo-cardiac disease to spoil the rhythm of the heart's sound, there was no assignable cause for the present train of symptoms. However, the country practitioner deemed it advisable to put him under treatment, as though cerebral disease was slowly advancing: he was cupped, blistered, bled, and kept very low; but he derived no benefit whatever from this course of practice. His varying symptoms were narrowly watched; the numbness would suddenly leave one arm and attack the opposite, and remain there for some days. It was considered at the time that the disturbance in that "nicely balanced engine," the heart, might account for these nervous ailments, and the attention of his physician, Dr. Mervyn Crawford was more particularly directed to this organ: he took digitalis with some transient benefit; was occasionally blistered and cupped to the head and neck; but still the disease remained unabated.

I must here pause a short time, and digress somewhat from the subject immediately before me, in order to relate the following curious circumstance.

It is now upwards of two years ago when Dr. Hawkins admitted into the physicians' wards a fat, chubby, and rosy-faced girl from the country, who had been sent up by her master, although she presented the picture of health, on account of a "nasty, disagreeable" cough, which so disturbed the servants, nay, the whole family, that she was quite unfit for his service. She ate, drank, and slept heartily enough; but, when this fit of coughing seized her, it rang through your head, and was almost insupportable. However, it proved equally as obstinate in the wards of the Middlesex, as in the country village. She had been with us upwards of three weeks, when, like most of our country patients who come in here with no very serious ailment, she was attacked with slight fever, sore throat, and headache—the result, as we believed, of confinement in a London hospital. Her physician, Dr. Hawkins, ordered a smart emetic, that it might cut short, if possible, the attack, and a brisk purgative at night; on the following day the nurse drew from under the bed a lumbricus, which she had passed, measuring three quarters of a foot. I need scarcely add that the girl soon left the hospital perfectly free from cough and every other ailment.

(To be continued.)

The population of Paris has increased from 1841 to 1846 118,636 individuals.

months old, whom I first saw about a month ago, was represented to me as having been ailing for four months; and that up to that period her general health had been good. Her appearance was like that of a child far advanced in droopy; emaciation very considerable, and abdomen exceedingly prominent. On my making particular inquiries, I ascertained that the secretion of urine was natural in quantity as well as in quality; that her bowels were regular, and her appetite good when she had potatoes, which she partook of eagerly, but that she refused every other article of food. I found her tongue clean, and pulse about a hundred, and moderately firm. When I examined her abdomen I was unable to detect any fluctuation; but, on the contrary, the taxis communicated the feeling of a firm elastic tumour, with an equal surface, extending from the sternum to the pubes. Death took place on the evening of the 11th ultimo, and I instituted a post-mortem examination on the following day, twenty-four hours after death.

Decomposition had already commenced, the abdominal parietes being much discoloured. On making an incision midway between the umbilicus and the ensiform cartilage, a portion of the colon protruded, filled with gas; and immediately behind it an enormous tumour made its appearance, occupying nearly the whole cavity of the abdomen. It was firmly attached

the perineum on the right side throughout its whole extent; partially so to the left, to the sacrum and lumbar vertebrae; and above, to the diaphragm.

When the mass was removed I carefully weighed it. Its weight was seven pounds and two ounces, and twenty-four inches in circumference, being nearly globular; its surface traversed by a multitude of blood-vessels, some of them of considerable size. On cutting open this tumour, I discovered it to be the kidney, the lower half of which appeared to be healthy in its structure, and capable of performing its office of secretion; the ureter, also, being healthy and pervious throughout its course to the bladder. The upper half, however, was one mass of disease, enclosed by an enormous sac; its appearance was brainlike; its consistence pulpy, interspersed with numerous cysts, from the size of a pea to that of a large walnut; some of them contained straw-coloured serum; others, especially the larger ones, serum of a bloody colour. Besides these cysts, there were lying loosely several clots of coagulated blood; the whole assuming very much the aspect of fungus hæmatodes. I may observe, in conclusion, that the contents of the sac were not uniformly of a pulpy nature, but intersected throughout its substance with numerous membranous bands, which, in some parts, were strong and unyielding to moderate pressure, and easily broken down in others. The whole of the fluid that escaped during the examination must have amounted to more than two pints.

POISONING FROM THE SEEDS OF THE DATURA STRAMONIUM.

Communicated by A. STOBO, Esq., M.R.C.S.

C. B., about five years old, a stout, healthy boy, the son of Musta parents, ate more than a drachm of the seeds of the datura stramonium taken from the fresh apple in a state of ripeness; the seeds had been slightly roasted on an old tin vessel over the fire. When seen, about an hour after, he appeared much excited and rather delirious, under the impression of some immediate danger, clinging to the person who had him on her lap. Pulse about 120; face flushed; eyes of a peculiarly dazzling lustre, pupils dilated; convulsive motion of the limbs and neck; thick frothy saliva about the mouth. He had been put into a warm bath, and had been given a dose of calomel before my visit at 11.30 A.M. Ten grains of sulph. zinc, and ten of ipecacuanha, were immediately given. No effect being produced in about twenty minutes, 3ss. sulph. zinc was given: slight effects at vomiting came on, and a

piece of soursop (*anona muricata*), with masticated portions of the seeds of the stramonium adhering, was brought up. I thought it prudent, under the circumstances, to use the stomach-pump: about a quart of tepid water was injected, when the stomach began to act freely; a quantity of soursop pulp and half-digested food, mixed with the seeds of stramonium, came away: a large injection of soap and water was thrown up the rectum, but was returned immediately unmixed with feces. An ounce of castor-oil was retained on the stomach, and in two hours operated freely. The seeds of stramonium were plentifully mixed with feces discharged. The boy seemed relieved for the moment; the eyes were in the same state; the toasting about of the limbs was rather increased; the pulse had risen in volume and frequency, with much flushing of the face, &c.; the skin, naturally of a pale olive, became of a bright copper colour; the temperature of the body was much increased.

Two P.M. Took ten ounces of blood from the arm, and ordered another ounce of castor-oil. Symptoms abated after the bleeding.

Four P.M. Symptoms more intense than at two o'clock; took away six ounces of blood from former orifice; bowels freely open; stramonium seeds still mixed with the feces; pupils less dilated. Cold epithems to the head, and diluent drinks.

Ten P.M. Pulse about 100; skin and head cool; appearance of terror worn off, but in its place maniacal vigilium, unceasing motion, and a disposition to sing. A little tinct. opii added to the epithems.

10. Has not slept during the night; pulse 98; skin cool; eyes more natural; has been constantly moving over his mattress singing or talking; bowels have been moved; no further appearance of seeds. The restlessness wore away during the day. A draught with liq. opii sedat., spt. eth. nit. with aq. camph., at bedtime.

20, six A.M. Slept well during the night, asked for food on awaking; except a slight idiotic expression, the usual state of health restored, only a little reduced; no paralysis nor other bad symptom has supervened in this case.

Tortola, West Indies, Aug. 28, 1817.

PROGRESS OF MEDICAL SCIENCE.

ACADEMY OF MEDICINE.

Meeting of Sept. 21; M. BEGIN in the Chair.

THE INVENTORS OF ETHER.

A letter was read from the French Consul at Boston, asserting that he had arrived at the conviction that the credit of the discovery of the hypnotic properties of ether was due to Mr. Morton, and not to Dr. Jackson. The secret had been sold to the latter gentleman for the sum of 5000 dollars.

The letter was referred to the commission appointed for the investigation of the newly-observed virtues of ether.

LITHOTRITY AND LITHOTOMY.

M. Blandin, examining the statistics brought forward by M. Civiale, remarked that the cases in which the crushing of the stone had not been entirely completed, were struck off of the tables by M. Civiale, and that it was, however, indispensable to take them into account. Instruments were introduced and opened within the bladder; laborious investigations were submitted to; the calculus was seized, occasionally a portion of it was removed; and, the operation being afterwards for one reason or for another abandoned, the case was not to be looked upon as one of lithotritry! This M. Blandin argued was not fair: such patients were afterwards cut; and who would dare assert that the dangers inherent to cystotomy were not very materially enhanced by the previous attempts at crushing? Lithotomy was certainly, now-a-days, followed by more fatal results than formerly; but why? Because the cases in which that operation was now performed were those which lithotriptic surgeons had al-

ready manipulated, or rejected as offering but slender chances of success. M. Civiale was of opinion that after cystotomy relapses were of more frequent occurrence than after lithotritry; M. Blandin was of an opposite way of thinking, and for the following reasons:—A calculous diathesis, a permanent irritation of the urinary organs, or the abandonment of fragments of concretions in the bladder, were the circumstances which favoured a relapse. Now, the first of these conditions, viz., a calculous diathesis, was totally independent of the method employed, and the chances of its existence were equal with both. Irritation of the urinary viscera was more permanent after lithotritry than after cystotomy, and fragments of stone were more likely to be left in the bladder when the former method was employed than when the latter was resorted to. It was, M. Blandin asserted, at present impossible to form a correct notion of the comparative advantages of the two methods, because modern cases of cystotomy could not be placed on the same line with those observed before the introduction of lithotritry into science.

M. Malgaigne considered the question now before the academy as one of the most important which could possibly be agitated. Public opinion had in a great measure pronounced, and, for his part, he did not hesitate to say that, if ever he had the misfortune of being affected with the stone, he would submit to lithotritry in preference to cystotomy. It was at the bedside of the patient only that the question of pre-eminence between the two methods could possibly be discussed; a debate on this point in an academy could lead only to negative results. The matter assumed a most serious aspect, if the relative and alleged mortality of the two systems was taken into consideration. If it was really true that M. Civiale cured ninety-eight out of one hundred patients, surgeons who operated in another manner, by cystotomy, losing more than half the cases placed in their hands, must have a very accommodating conscience if they could allow themselves to rest quiet before they had sifted the matter to the bottom. M. Malgaigne had felt deeply upon this subject, and, having made it his business to examine carefully into the various statistics brought forward, had acquired the conviction that none were entitled to any credit either in France or abroad. They were mostly collected from badly-kept hospital day-books, and did not bear a close examination. From a small number of recently-observed operations, M. Malgaigne concluded that, now-a-days, two cases were lost out of every five in which cystotomy was performed, and one only out of every five in which the calculus was crushed. The number of fatal cases was smaller in private practice than in hospitals, on account of the bad ventilation of the greater part of the sickwards. Finally, M. Malgaigne defended strongly lithotritry, but not the results brought forward by M. Civiale, which he thought were much exaggerated; but he considered it the duty of the surgeon always to endeavour to crush the concretions before any attempt was made to remove them by cystotomy.—Meeting adjourned at five o'clock.

SCLEREMA OF THE ADULT.—CASE BY DR. BOUCHUT.—L. C., a house-painter, aged thirty-two, having greatly overheated himself during a fire, on the 22nd of June, remained for several hours in a cold passage open to every wind, and returned to his daily labour. The next day he experienced some stiffness in his limbs, which increased to such an extent that after four days he was obliged to leave it off. The movements of the head, arms, and body had become very difficult, and the skin had acquired a degree of hardness extremely remarkable. Its colour was not changed, nor was it the seat of any heat or pain, but it was as hard as marble on the face, arms, body, and scrotum. The jaws were almost immovable; the shoulders, elbows, wrists, and fingers were fixed as firmly as if they were affected with ankylosis; the efforts to overcome this rigidity were attended with pain, but no tenderness of the parts was observed on pressure.

The penis was in a state of painful erection during the night, sensation was preserved all over the body, and the perspiratory function was not in the least impaired. The appetite was unchanged, the digestive powers natural, and no febrile excitement existed. Stimulating frictions were performed upon the skin, the bowels were opened with two brisk purgatives, and a blister was placed behind the neck. These measures were productive of some amelioration, but a complete cure has not yet been obtained. The following is the present condition of the patient, as represented by Dr. Bouchut in the *Gazette Médicale* of September 25:—The induration of the skin still persists, though in a less marked degree; the head, forehead, cheeks, chin, and neck are very hard; the eyelids and lips have gradually recovered their natural softness; the jaw is still almost immovable; the movements of the neck are absolutely impossible. The skin of the thorax is as hard as that of a frozen subject; the skin of the fingers and hands has resumed its softness, but the mobility of the shoulders remains very limited. The pelvic extremities are in a healthy condition; some trace of the induration may, however, be noticed upon the legs, but the skin can be pinched between the fingers, which it is impossible to do on the arms, neck, or body. The temperature of the body is not below its usual degree. The general health remains satisfactory.

ACADEMY OF SCIENCES.

Meeting of Sept. 27; M. BRONGNIART in the Chair. INTOXICATION BY THE VAPOURS DISENGAGED IN BRASS FOUNDRIES. BY DR. REBOULLEAU.

The author, having had occasion to observe the morbid symptoms resulting from this cause, describes them as follows:—At first a dull pain is experienced in the hypochondria and in the lumbar region; loss of appetite, oppression, and weariness of the limbs; a chill and general uneasiness are alone afterwards noticed; the pulse is small, frequent, and irregular; nausea and vomiting occasionally appear, and general heat and perspiration usually follow. This crisis lasts from eight to ten hours, and closely resembles a paroxysm of intermittent fever. It is during the night that the attack generally takes place, and it reappears four or five times, particularly during damp weather.

The author attributes these effects to the metallic emanations from the foundries, and recommends the operation of casting to be performed in open sheds.

ACADEMY OF MEDICINE.

Meeting of Sept. 28; M. BROIN in the Chair.

CHOLERA.

M. Prus stated that, from a communication received that very day, no doubt could be entertained of the appearance of cholera at Moscow; Smolensk, Plescow, and Riga had also been attacked. It was further asserted that the city of Odessa had been visited in a similar manner. If the information received was correct, cholera had in a very short space of time travelled over a space of 700 leagues (1750 miles). It was not right to create false alarm, but it would be unjustifiable not to take beforehand some precaution against the probable invasion of the scourge; it was the duty of the Academy of Medicine to point out the measures which might prevent, or delay its apparition, or, at least, render the disease less murderous. An important circumstance, in the eyes of Dr. Prus, was the extraordinary abundance of fruit during the present year.

M. Girardin remarked that, when cholera had invaded Russia in 1830 and 1831, it had followed two directions perfectly similar to those it now adopted.

M. Prus added that the disease did not show itself with the same violence as in 1831.

M. Rochoux said that, if anything was proved, it was the complete ignorance of the profession relatively to the causes of cholera. Its progress also was a circumstance which it was totally

impossible to foresee. What useful measures could, therefore, be proposed?

CYSTOTOMY AND LITHOTRITY.

M. Civiale read a long paper, in which, without introducing any new matter, he endeavoured to defend his previous assertions against the criticisms of MM. Velpeau and Blandin.

M. Velpeau, in his answer, again endeavoured to show the inexactness of M. Civiale's mode of establishing statistics; but the debate, not offering a single new feature, and remaining within the limits of a positive assertion on one side, and of as positive a denial on the other, presented but slender interest to the wearied audience.

Meeting adjourned at five.

POISONING BY ARSENIC.—**DIAGNOSIS.**—Dr. Legroux was recently called in to attend a young person who presented the most alarming symptoms of poisoning. The patient refused to acknowledge the nature of the poison which had been taken, the motions and the matter rejected from the stomach having been incautiously thrown away. M. Legroux applied a blister, and the serosity which was thus produced yielded to the chemist, after destruction of its organic matter, sixteen arsenical stains.

VARICOCELE—OPERATIONS.—M. Ricord's operation for the cure of this disease consists in the "subcutaneous ligation of the vessels," and is performed in the following manner:—The veins being carefully separated from the vas deferens, easily recognised by its cartilaginous consistency, a needle armed with a double thread is passed through the skin, under the veins, and issues again out of the skin, in such a manner as to leave on one side a loop, and on the other the two extremities of the silk thread; a second needle, similarly charged with a double thread, is passed through the same apertures of the skin, but between the veins and the cutaneous envelope of the scrotum, and follows a contrary direction to that given to the first ligature, so as to leave a loop on the side, from which issue the extremities of the first thread, and reciprocally its extremities on the same side with the loop of the other ligature; the threads are then passed through the loops, and drawn tightly in a horizontal direction, and the subcutaneous ligation is effected. At the end of one week, or of ten days at the furthest, the ligature is removed in the simplest manner, and frequently without division of the veins: by merely drawing one of the threads which hang at either side the knot is immediately loosened. We have seen many applications of this method; we have ourselves performed the operation; and, although a vast number of cases have now been submitted to it, we do not know of a single one in which it has been productive of accidents, we do not say fatal, but even sufficiently serious to warrant anxiety.

ULNAR ARTERY.—For the ligation of the ulnar artery the forearm is usually flexed upon the arm. M. Malgaigne deprecates this practice for the following reasons:—The ulnar artery descends to the wrist, between the flexor carpi ulnaris and the flexor digitorum sublimis: it is besides, covered by the skin and fascia; if the forearm is bent, the position of the artery becomes still deeper by the protrusion of the tendon of the flexor carpi ulnaris. Extension of the forearm, and forced supination of the hand, on the contrary, cause this tendon to retire backwards, and render the position of the artery so superficial that it can readily be felt, and that its pulsations may even be frequently seen.—*Revue Med. Chirurgicale.*

HYDROPHOBIA.—**CASE.**—A child, aged eight years, was bit in the hand by a little dog on the 26th of August. The dog died on the 27th with symptoms of hydrophobia, after having also bit a girl, who was taken to an apothecary. Her wound was not cauterized, but a draught was exhibited, warranted to prevent the ill effects of the accident. Fortunately no signs of hydrophobia have hitherto made their appearance. The wound in the hand of the boy was poulticed; but, the fears of the family being excited, he was brought on the 27th to Dr. Blatin, who found at the basis of the nail of the right medius finger a

small lacerated wound, six millimètres in length and one or two in depth; its neighbourhood was purple, and tender on pressure; the axillary glands were free from any swelling or pain, and the child appeared in every other respect perfectly healthy. A circular ligature being applied on the finger above the wound, a large drop of purulent and sanguineous matter exuded; the laceration was enlarged with the knife, and caustic potash was applied to the whole surface. During each of the two following days the cauterization was renewed, the eschar being previously removed. On the sixth day the parts were healed, and for three weeks no alteration of the child's general health was observed. On September 20 (twenty-six days after the accident) the child was seized with agitation and trembling; at night attacks of suffocation made their appearance, deglutition became impossible, and during two hours a characteristic crisis of terror, hallucination, sobbing, and hysterical laughter was observed, and was followed by a period of quiet which lasted half an hour. The throat was then examined: the pharynx and velum were of a deep red colour, and an abscess was found in each tonsil. A bath and pediluvium were prescribed, and the child was kept in the water only by the exercise of main force. From that time forward the alternacies of delirium and violence, the continual sputation, sobbing, and repulsion for bright objects and for fluids were unceasing. Another day and night were spent in this condition, and death occurred suddenly during a violent tetanic convulsion. The wound and the arm had not been the seat of any pain or swelling. From the first the pupils were much dilated, and remained insensible to the strongest light. No trace of pustules was observed on or under the tongue, and a loud rhonchus was heard in the chest. During the spasmodic attacks the pulse rose to 150, and in the intervals was never above 100; the abdomen was soft until the last twenty-four hours, when it acquired from flatulency a considerable development. The treatment consisted in the daily exhibition of muriate of morphia (two grains in several doses) and a few grains of calomel, which occasioned the expulsion of a considerable number of small worms. Inhalation of ether was prevented only by the sudden death of the patient.

D. M'CARTHY, D.M.P.

REVIEWS.

Report of the Inquest on Miss Sophia Dallett, held at Putney on the 6th and 14th of July, 1847; printed from the Notes of one of the Jury, with an Appendix. Edited by JOHN ROSE CORMACK, M.D. Edin., F.R.S.E.; Fellow of the Royal College of Physicians of Edinburgh; late Physician to the Royal Infirmary of Edinburgh; Physician to the College for Civil Engineers, Putney, &c. &c. Churchill, Princes-street, Soho.

When are we to see the last of this unseemly feud? In the name of belligerent Physic, which should now be satisfied *ad nauseum*—in the name of common sense, which has long since assigned its meed to each actor in the tragedy—we reiterate, when are we to see the last of this unseemly feud?

A pamphlet on the Putney Inquest! What can Dr. Cormack have been doing, to require such a costly vindication?

The case stands briefly thus: Sophia Dallett, a young lady, in her fifteenth year, was attacked on Thursday, July 1st, by symptoms which her family conceived to be of a bilious character; to remedy these, a couple of antibilious pills were administered, and the dose repeated on the following day. Sunday, finding her no better, Mr. Farmer, the chemist and author of the antibilious pills mentioned, was applied to, and he furnished "four grains of grey powder to be taken at bedtime, and a common black draught

for the morning." The morning found her no better—the evening worse. The powder of the previous evening had been returned, and the draught had had but little effect. The public have faith in a remedy in the ratio in which it acts on their bowels. The doses were repeated, with the addition of a saline mixture, that same evening, and on Tuesday morning. Sickness did not recur, and the draught operated, "neither violently nor gently," in an hour. The patient now became very low, some alarm was excited, and Dr. Cormack was summoned. He saw her three times on that day (Tuesday). Repeated and violent sickness, and increasing abdominal pain, were the symptoms. Dr. Cormack considered the case "probably a low fever," and that the previous medicine "had been perhaps too searching." His treatment consisted of homœopathic doses of a narcotic (hydrochlorate of morphia), and of a "diffusible stimulant," in the shape of camphor mixture. Creasote mixture (Ph. Edin.) was given to check the sickness. Subsequently these forms were substituted:—Opium and extract of henbane, of each half a grain, divided into three pills, one to be taken every hour; and an external "diffusible stimulant," composed of spirits of turpentine and liniment of the sesqui-carbonate of ammonia, of each five drachms, laudanum two drachms, to be applied to the abdomen by means of a piece of flannel. At the last visit (8 P.M.) ginger-beer powders were considered indicated, and effervescing draughts nearly so. Wine was directed to be given should faintness supervene. The symptoms were altogether alleviated. Between four and five, however, on the following morning (Wednesday) Dr. Cormack's attendance being promptly sought, he found his patient in a state of "stupor and collapse," which he thought "as just possible (the italics are his own) to have arisen from the absorption of the opium of the liniment;" whereupon he, and the friends he called in to his aid subsequently, set to work in right earnest to apply the means for recovery from narcotism: the poor girl was hauled from room to room; mercilessly slapped; her throat tickled; sulphate of zinc administered as an emetic; the stomach-pump on the point of being applied, when death closed the scene.

The reflections drawn from this case are in favour of nobody. Dr. Cormack's patient died either of narcotism, or of collapse. His treatment of fever, as he suspected; of peritonitis, as he dreaded; cholera, as he half imagined, was strange enough. But we will not say more for it—more than that, in the squabble into which he has managed to involve himself with the chemist and the medical juror on the occasion, there is no gain of professional dignity. At any rate, legitimate medicine neither stands nor falls with the deserts of Dr. Cormack. His practice is certainly not that of our London physicians.

TO CORRESPONDENTS.

THE MEDICAL TIMES may be procured by an order on any Newsmen or Bookseller, or it will be sent direct by post from the Office of the Medical Times to Subscribers sending by a Post-office order, directed James Angerstein Carfrae, or an order on some party in town, One Guinea IN ADVANCE, which will free them for twelve months. Half-yearly Subscription, 13s.; Quarterly, 6s. 6d.

E. M. Alpha.—We think Denman's as good as any.

An Army Surgeon writes—"John Pringle was one of the brightest ornaments of our department, and many will be jealous of any attempt to deprive us of the lustre reflected by his great reputation. Had Mr. Emerson taken the trouble to read the whole of the titlepage, he would have seen the work was a translation, and might then have given the quotation in the original, which is always desirable,

but especially when quoting from works in the mother tongue.

Mr. S. Aston Williams sends us a printed circular of a Mr. R. Smith, "who begs most respectfully to inform the inhabitants of Westbourne-grove and its vicinity, that he has taken the above villa, where he intends practising the different branches of his profession. R. S. begs to state, that any lady or gentleman consulting a physician can have their prescriptions most accurately prepared." Who can wonder that the members of the profession are treated with contempt by persons in authority. The defect lies in the education, not only professional but the general, which must be elevated.

A Subscriber, Robeiglass.—We fear there will be great difficulties in the way of obtaining fee for attendance.

An Old Subscriber may obtain all the information he seeks by calling at the East India-house.

C. M. is thanked for the information, which is under consideration.

Gottingen.—We think the College has the power.

J. W., Clapham.—We are not aware of the amount of salary, but an application at the office in Scotland-yard will be the means of obtaining all the information.

Dr. R. De Gumbleton Daunt.—The communication has been received.

Sigma.—The school is respectable, and the lecturers well adapted to impart instruction in the various sciences to which they especially devote their attention.

Mr. J. S. Brenton.—A private communication has been sent.

Teetotaler.—It is not our province to discuss the subject. Water is certainly a very good thing.

Delta.—Our correspondent will oblige us by communicating to us his address.

A Pupil cannot do better than provide himself with South's edition of *Cheilus*—the most complete work we have on surgery.

Mr. Henley desires to acknowledge, through our columns, the receipt, towards the expenses of the Poor-law Convention, of half a guinea from Dr. Hinds, of Birmingham, as also a subscription of one guinea from Mr. Alfred Ebsworth, of Nottingham. The numerous communications with which he has been favoured on this subject have been acknowledged privately.

A Pupil of Mr. Dermott.—We are much obliged for the communication, but from peculiar circumstances think its publication inexpedient.

Poor-law Unions.—Mr. Hardwick, M.R.C.S. and L.A.C., of Hemphall, thus addresses us:—"For the spirited conduct of your journal in exposing everything mean and disreputable connected with our profession, and for its noble advocacy of the best interests of that profession, I beg you will accept my warmest thanks. Your present step of exposing the meanness and injustice of ignorant administrators of the poor law, as regards medical remuneration, is quite exhilarating. Unfortunately, I am one of that injured and oppressed party, and will never fail to raise my cry stenorian until something be done to ameliorate our condition. By looking into my books, I find I have been attending and supplying with everything needful, upon the average of the last three years, four hundred and ninety-two cases per annum for the great consideration of £40. 2s. per annum."

Dr. Krug on Boro-tartaric Acid.—We are indebted for this interesting paper (including the translating) to the kindness of our able and much-esteemed correspondent Dr. Daunt, of Campinas.

Letters and communications have been received from Mr. Casey, St. Helen's; Mr. Hastings, Stoke Church; Mr. Whittle, Brunchley; Dr. Sheehan, Buttevant; Mr. Havoks, Thorpe; Mr. Cocks, Harlow; Mr. Cusworth, Alost; Mr. Allen, Epsom; Mr. Butterworth, Rochdale; Dr. Ogilvie, Aberdeen; Mr. Grewcock, Falkingham; E. M. Alpha; An Army Surgeon; Mr. S. Aston Williams; An Old Subscriber; C. M.; Gottingen; J. W., Clapham; Dr. R. De Gumbleton Daunt; Sigma; Mr. J. S. Brenton; Teetotaler; Delta; A Pupil; A Pupil of Mr. Dermott.

THE MEDICAL TIMES.

SATURDAY, OCTOBER 9, 1847.

MEDICAL STUDENTS.

"Recreation's season over,
Labour now demands your care;
Grant it—you will soon discover
What its rich requitals are."

COLESWORTH.

THE above quaint motto, from an intelligent, if not an erudite, author, is intended to apply to the obligations which at this season hold between medical students and the profession of which they have chosen to become the future representatives. We promised in our last article on this subject to say a few more words thereon in the present number, and thus runneth our discourse.

We are not intending to present it according to any of those stupid old forms of division and subdivision, *à-propos* of nothing for which junior parsons, unrequited patriots, and apprentice-boy declaimers are chiefly remarkable. We intend to follow no particular style, arrangement, or mode of reasoning whatever: we simply mean to have a few words of utterance, as near the truth as we can get them, and be utterly indifferent to the particular form or feature which the delivery of this said truth may be invested with.

Our first object will be to say current something about medical students as they are often found; and then a few things more concerning the habits and manners that should be peculiarly theirs.

We have a great objection to epithets—they are excessively vulgar things, more easily got than lost, and particularly apt to stick to the individual they may happen to be thrown at all the days of his life. For this reason we do not intend to apply any denominatives distinctive of the students upon whose characters we make the following running comments.

To call them this, that, or the other, according to the established slang of the day, might be giving to some biped piece of impudence the opportunity of conferring a nickname long after the individual it related to had ceased to deserve it.

Without, therefore, using appellatives of any kind, we will proceed to say that there are various shades of difference for which medical students are remarkable. We do not know whether they are more unlike one another, the mass through, than any of the uninitiated of other learned bodies: perhaps they are not; but it little matters, seeing that they are curious enough to deserve criticism in the abstract, and without any reference whatever to other popular somebodies whom they may distantly resemble.

Now, there is a student, complimentarily so called, who is chiefly known from an approach to his likeness appearing upon one of the flash songs of the day. He wears a glazed hat, low in the crown; a pilot coat, ornamented with buttons like little trenchers; his neck is carelessly girded with a silk or worsted something, in which the deepest possible colours are run together in the greatest possible contrast; he wears no straps, and rejoices in a pair of boots whose soles are celebrated for the number of shins they have kicked; he looks upon gloves as foppish and effeminate, and considers a stick like a hedge-stake to be a *sine qua non* to the out-door respectability of a gentleman; he reads the slang dictionary, and swears like a carman; he regales

himself with half-and-half before breakfast, and covers his supper with sundry potatoes of whisky-toddy; he goes half-price to the minor theatres, and is fond of winding-up at Evans', or "the Finish;" he is ready for a "rubber" with anybody, and prizes his meerschaum above his money; he bets in a small way, knows the odds upon everything from the racecourse to the ring, and is devoted to the study of *Bell's Life in London*. As a natural consequence of the aforesaid freaks, his professional duties receive little share of his attention. One of two things happens: he runs the usual course of time allotted to studentship, gets rejected, and betakes himself to another calling; or he suddenly renounces his bad habits, works with as much energy as he played aforesaid, passes a creditable examination, and merges into business a respectable practitioner! We have known many such cases, and therefore never cease to hope the best things of the character above detailed, so long as a chance is left for him. But he plays a game that is dangerous to trifle with: to such man, and every such, we say—*carpe diem*! As no man can better apply the motto, none can be more fitted for translating it.

There is another student—affectedly one we mean—who vastly resembles the above in some particulars, and differs as much from him in others. The resemblance is in attending to anything but his proper business; the difference is in the objects that divert him from it. This gentleman belongs to the fashionable world—at least he thinks so. Some silly acquaintance in the country has given him half-a-dozen town introductions, and thus paved the way for well-nigh ruining him. He plumps all at once into a consequence that forms a strange contrast with the modesty, retirement, and industry that would better become him. Considerable of the money that his parents intended to pay for his rooms and his victuals finds its way at once into the pockets of certain outfitters who have an extemporaneous process for making the external man of a provincial look like that of a cockney. He cultivates a moustache; carries a snuff-box and dress-cane; makes morning calls *à la mode*; and passes his evenings at parties or fashionable places of amusement. He does not associate with his fellow-students—they are too low; he never reads a medical book—it's a bore; nor enters the dissecting-room—it's so filthy; nor attends lectures—they're so tedious. He rises when common people are eating their dinners, and boasts of going to bed by daylight. At home he was as long-sighted as a lynx; but his optics have suddenly changed their anatomy, and an eyeglass has become indispensable: he grins at the girls through this piece of crystal, which he considers a necessary appendage to the dress of a gentleman.

The career of this youngster terminates variously. A timely stoppage of the supplies will sometimes bring him to his senses, and set him on right earnest about redeeming the opportunities he has lost: if he have gone beyond convenient redemption, he may find his way into the army, or betake himself to the stage. The unexpected visit of his father, and of a horse-whip, has been known to be very efficacious in promoting, in his personal habits, a sanitary reform. In some cases his pursuits vary little from what we have related, excepting that, towards the end of the chapter, he gives an hour of every day to a process of cramming for examination. If he fail in this, anything may become of him, it matters little what; if by good luck he pass it,

he forthwith pledges himself to obligations which he is utterly incompetent to fulfil. The world quickly finds him out: he is fortunate, if inheriting a patrimony that suffices to keep him, for, in nine cases out of ten, he is not capable of keeping himself.

Between these extremes, there are various shades of student-character commonly met with. They are not so conspicuous as those just mentioned, but still they are things to take warning from. There is the thoroughly idle man, for instance: he is no pursuer of high life, or low life, or dissipation of any kind, for he would not be at the trouble these things cost—he is fairly idle, and nothing else. He is not frightened at his books, for he will go to sleep over them at any time; his plan is, never to do to-day what he can possibly put off until to-morrow, and never to do himself what he can get anybody else to do for him. He likes nothing better than eating and drinking, except a nice lazy yawn, or what he calls a "jolly good snooze." He gets fat, and rejoices that nothing troubles him.

Then there's the social student: he is full of anecdote; tells a pleasant tale; and sings a merry song. He has a regular round of acquaintance, who are perpetually inviting him for his feats of conviviality. He is the diner-out of his class: for, amongst those who know him, a dinner is not complete unless his toasts and sentiments, and songs, are accessory thereto. These things are all very well in their way—that is, when they don't stand in the way of anything better. But with the student they too often do. A fine voice is fatal to a man who has to get his living by other means than its exercise. The song leads to the glass, and from simple conviviality comes the direct dissipation.

Then there's the man with a genius, or what he considers one. This fellow is too clever for anything. Study with him is, of course, out of the question: he does not need it: the slow processes by which common people get knowledge, he despises: his wits are at his fingers' ends—he has an intuitive acquaintance with everything—he is the victim, in fact, of over-sharpness. He always gets rejected, which he properly attributes to the examiners not having sense enough to understand him.

There's that common being, again, who is always about to begin his studies, but never does so. He has got his books in order, and all other things preparatory to business, except himself. He is the only commodity that is never forthcoming when he ought to be. Yet he never abandons the idea of work, and would be mightily offended if you called him idle. Like an itinerant showman, he is always "just going to begin," but he never goes further than this. If you meet him in the street, and ask what he is studying, he gets excited all in a moment, and tells you he is about to commence such or such a thing in downright earnest; and off he sets, as though he meant it. Poor fellow! all his time is occupied in forming good intentions.

In the enumeration of the several faults and foibles of these several characters, we have shown to the student the particular evils that are liable to befall him. We have shown him what he ought not to be—he will easily understand that the opposite of these things will best become him. A modest and proper estimate of his own importance will preserve him from rudeness and vulgarity on the one hand, and from conceit and feppery on the other. The brawling occupant of the pothouse is not further from the decency of

the well-bred gentleman than is the empty frippery of the coxcomb from his dignity.

The student should never lose sight of the magnitude and moral responsibility of his professional obligations. Keeping these serious truths constantly before him will be the surest means of incitement to unyielding exertion in the acquisition of knowledge. Lectures may be tedious, and books may be dry, and dissecting may be disagreeable, and hospital practice may be troublesome, but the end of these things should be looked at; and, if regarded faithfully, it will ever be a qualification of the unpleasantness of the means.

The student should love his profession with all his heart—love its noble purposes and projects, and be thankful for the opportunities about to be afforded him of being one amongst those who are honoured in the occasion of doing good to his fellow-creatures. This high honour and happiness will in future be his proportionately to the efforts he may now make to qualify himself for deserving it.

CONVENTION OF POOR-LAW DOCTORS.

This project assumes every hour more the shape of an event decided on and certain. The various existing agencies in reference to poor-law relief have come to a mutual understanding, and, in order to allow full time for the efficient working of this happy combination, it has been determined not to hold the Convention till about Wednesday, the 27th inst. That there may be no misunderstanding or mistake, full information will be conveyed, on an early day, to every union doctor by private circular and public advertisement.

Our readers know that the Provincial Association appointed a committee on this question at the last public meeting. The committee included, among other respected names, those of Dr. Hodgkin, Mr. Martin, and Mr. Cantrell. They are aware also that the Council of the National Institute have expressed a warm anxiety in the success of the agitation, and have liberally placed their rooms at the disposal of its originators. We are happy to announce that a requisition for the Convention is by this time nearly ready, signed jointly by gentlemen, principally union surgeons, connected with both these associations, and by union surgeons not belonging, as members, to either body.

We consider a requisition of this comprehensive character useful, not so much for any actual necessity of such a mode of procedure, as for the guarantee it gives us that the Convention, once called, will receive, in the course of policy it may in its wisdom lay down, the harmonized influence and power of the most important medical combinations existing in this country.

It is proposed, therefore, to avail ourselves of the zealous co-operation of the authorities of the Provincial Association, as well as of those of the National Institute; and the Convention will be held in the rooms so handsomely offered by the latter body.

The requisition, as we understand, runs thus:—

"We, the undersigned, being persons interested in the amelioration of poor-law medical relief, hereby call a General Convention of Poor-law Surgeons, to be held on Wednesday, the 27th of October, at three o'clock p.m., at the Hanover-square Rooms, which have been handsomely placed at the service of the undersigned for such purpose by the National Institute of Medicine; and the undersigned strongly recommend imme-

diately special meetings of poor-law surgeons in their several unions and districts, for the purpose of collecting data to be submitted to, and of appointing delegates to attend, such Convention; and also earnestly invite all poor-law surgeons, whether appointed as delegates or not, to give the Convention the advantage of their attendance, where practicable. [Here follow the signatures.]

"Communications may be addressed, in the meantime, to Thomas Hodgkin, M.D., Brook-street, Grosvenor-square; to T. Martin, Esq., Reigate; to W. Cantrell, Esq., Wicksworth; to George Ross, Esq., secretary to the National Institute, Hanover-square Rooms; and to T. Piers Healey, Esq., No. 43, Connaught-square, London, who has kindly undertaken the duty of Hon. Secretary."

The many poor-law surgeons who wish to attach their signatures to this requisition, to be in time, should send their authorizations by the very next post. The document cannot be too largely signed; nor could an autograph be dedicated to a better service.

The delay in holding the Convention will have some other good effects. It will allow union doctors to get up and systematize their data; as also to hold in the interval sectional meetings of unions and districts, to publish their opinions through resolutions, and to appoint delegates to attend the Convention. As one of our respected and active correspondents, Mr. H. Livett, says, "this will save much talk—mere useless talk."

Already we have had three sectional meetings of this useful character. The first was held by Messrs. Cantrell, Tasker, and others, in the neighbourhood of Derby. The second was held in the Town-hall, Wells, on Sept. 30, Mr. Livett in the chair. The following were the resolutions:—

"1st. On the motion of Mr. Prankerd, of Langport:

"That this meeting considers the present rate of remuneration to union medical officers to be, in most cases, inadequate; and, inasmuch as in different unions different salaries are paid for the same services, that it is likewise very unequal; and that some steps should be taken by the parties interested to endeavour to remedy these evils."

"2nd. On the motion of Mr. Hudson, of Shepton Mallett:

"That, as it would be useless and only productive of ill feeling and unpleasantness to apply for a remedy to local boards, this meeting considers the commissioners and the Secretary of State for the Home Department the proper quarters in which to make known the grievance and to seek a remedy; and that a memorial presented to them, temperately setting forth the inequality and injustice of the present state of professional remuneration under the poor law, and requesting that some fixed principle be laid down, by which more adequate salaries may be regulated, and signed by the whole body of poor-law medical officers, would, now the commission is about to be remodelled, be well timed and likely to be productive of good results."

"3rd. On the motion of Mr. Furnivall, of Hutton, Weston-super-Mare:

"That this meeting agrees to adopt the following form of memorial; but considers that its presentation should be delayed for one month, to allow time for ascertaining whether a General Convention of poor law medical officers be practicable; as such a Convention would be the best means for ascertaining the sense of the whole body; and such a memorial would have much greater weight if presented with the concurrence of the whole, rather than that of a comparatively small section of the medical officers acting under the poor law."

A few days after October 2, a meeting of the

poor-law medical officers of the Basford union was held in Nottingham, when the following resolutions were passed:—

"Mr. ORTON, of Beeston, in the chair; Mr. NORMAN, of Ilkeston, vice-chairman.

"1st. Proposed by Mr. Longstaff, of Ilkeston, and seconded by Mr. Fowler, of Calverton:

"That this meeting, representing the feelings of the medical officers of the Basford Poor-law Union, deprecates the present inadequate salaries of the medical officers, sanctioned by the poor-law commissioners."

"2nd. Proposed by Mr. Ebsworth, Bulwell, and seconded by Mr. Graham, Basford:

"That this meeting is of opinion that a commission (a moiety consisting of medical men, acquainted with poor-law union practice) should be issued by Government to inquire into the subjects of the duties and remuneration of medical officers."

"3rd. Proposed by Mr. Norman, seconded by Mr. Longstaff:

"That, on careful investigation, it appears to us, that in the Basford Union the medical salaries are far inferior to those in most other unions, being scarcely equal in a single instance to the actual cost of drugs and horse expenses, and therefore preclude the possibility of the medical officers doing justice to themselves and the poor also."

"4th. Proposed by Mr. Fowler, seconded by Mr. Ebsworth:

"That copies of the returns furnished to this meeting by the several medical officers be forwarded to the poor-law commissioners and the board of guardians, with the view of inducing them, at the earliest possible period, to remove the grievances under which the medical officers of the Basford Union are now suffering."

"5th. Proposed by Mr. Longstaff, seconded by Mr. Graham:

"That this meeting is of opinion that the present fees allowed for vaccination in the Basford Union are so low as to render the the Vaccination Extension Act almost a nullity; and that no fee less than one shilling and sixpence will cause the act to be carried out in the spirit in which the Legislature intended."

"6th. Proposed by Mr. Longstaff, seconded by Mr. Ebsworth:

"That this meeting condemns the exclusion of burns, scalds, and other long-protracted and dangerous surgical cases from article 177 of the present Poor-law Regulations; and they are of opinion that the article 181 should have been more defined, and made imperative."

Mr. Ebsworth, who has done us the favour of communicating to us this report, and in whom our readers will recognise one of our well-known and clever correspondents, adds an assurance that one of the gentlemen attending the meeting will attend the Convention as a delegate.

It only remains for us to say, that the ball is now at the feet of the union surgeons, if they will only fearlessly and *honestly* do their duty. There must be no flinching from the pain, no shirking from the labours, of this duty. It is every man's interest equally—and therefore in honour should have every man's attention equally. To hang back in the hope, or chance, that others will do their work and ours, is neither just—nor prudent—nor, indeed, to add the truth—*gentlemanly*. A common injustice requires a common resistance—and this the more here, since involved with our interests and rights, are the first necessities of our poorer fellow-citizens. Let each union doctor then be up and stirring, and lend his fair share in bearing the heat and burden of the day.

There are persons—too—with something fiendish in their composition, who, having no interest in the present evils, will try their best at their maintenance, by sowing dissensions and distrusts, and by enfeebling and dividing our

concerted action. If they succeed—the fault again is ours. The very attempt is an insult to our understandings: but the triumph will be conclusive evidence that the insult has been well deserved.

PROPOSITION FOR IMPROVING PERFECTION AT THE LEICESTER INFIRMARY.

PUBLIC institutions, like individuals, become renowned in two ways—either by acts which redound to their credit, or by those which brand them with marks so ignominious as to make them mistrusted, despised, or condemned. Amongst the latter must be placed the unfortunate hospital at Norwich, with its lazy nurses and dirty towels; whilst amid the former, if we are to believe the testimony of some who advocate its claims, that peak of hospital perfection will be located, the Leicester Infirmary. This latter institution has been kept for a long series of years in unmerited oblivion, having, as we are informed, an "internal management as perfect as a human institution can be." This declaration, moreover, we ought to receive as "gospel," coming as it does from a gentleman who has obtained episcopal authority to exercise the sacred functions of the priest's office. Yet, by an unfortunate transmutation to which everything sublunary is exposed, the "cloth" which is *now* universally revered has been divested of that infallibility which was considered one of its attributes in a bygone age. In spite, therefore, of the clerical declaration of perfection in the management of the Leicester Infirmary, there have been some who have thought that its perfection might be made still more perfect by adding to the number of its medical and surgical staff. This has become the *questio resata*, having occupied the attention of a committee for the last twelve months, which had been especially appointed to compare the existing rules of the house with the practice then prevailing; to consider whether, and what, alterations might be necessary to *increase the efficiency* of the charity; and to promote the interests of medical and surgical sciences.

The committee, it appears, pursued its labours with great zeal and activity—met more than thirty times—accumulated evidence of the most important character, and a short time ago read its report to a meeting of the governors. There it was recommended that an additional physician and surgeon should be added to the establishment for the following reasons:—"It appears," says the report, "not to have been the practice of the honorary surgeons, and of their predecessors for many years, to meet the out-patients on the days of the attendance of the latter, after their first admission, and that whilst the persons whose cases the house-surgeon considered of the most importance were directed by him to go to the houses of the honorary surgeons, the remainder were left under his care; a state of things evidently at variance with the rules and the designs of the institution."

The practice seems to have arisen in consequence of Saturday being selected as the day for the attendance of the out-patients, which suited very well their convenience, but was so inconvenient to the surgeons as to render it impossible to give all that attention which the hospital patients required without neglecting those who, with fee in hand, could readily castigate any supposed neglect towards them by a withdrawal of their patronage. Moreover, the population of Lei-

cester, like most other towns, has greatly increased within the last few years; additions also have been made to the infirmary, so as to augment its means of affording relief to those who seek it, and yet no addition has been made to the number of medical officers. Under these circumstances the recommendation was made, which, at a meeting of the governors last week, afforded those present ample opportunities of doing the polite to their friends, and of displaying those oratorical powers with which nature and art had combined to endow them. There is something in these meetings, *per se*, which is truly amusing. Really excellent individuals are oftentimes not content with a simple display of their benevolence; they must also embellish it with a few ornaments which are considered as attributes of dignity. A little speechifying must be accomplished even when the knees smite together, and the tongue is paralyzed with a perturbation which renders sundry hums and aha requisite to the safe delivery of the oration with which the individual is pregnant, and travails in pain to be delivered. Whether Mr. Packe, who was a prominent orator at the meeting of the governors of the Leicester Infirmary, was so affected we are not prepared to say; but he delivered himself of an amazingly large speech, which, when divested of various cut and dried expressions, such as "sense of duty," "honest conviction," "valuable institution," "noble chairman," &c., might be popped into a nutshell. The sum and substance of the reverend gentleman's remarks were, that the infirmary ought to be carried on for the purposes of benefiting the poor only, and not with a view of promoting medical and surgical science; and that this could only be accomplished by rigidly adhering to the present order of things, to the exclusion of medical practitioners at present not attached to the institution, and of youths who are anxious to learn in the wards of a hospital that science which carries with it the best blessings to a sick population.

Mr. Packe forgot, in his zeal for his friends, when he exhorted the governors with deep pathos "to let well alone," that no class derives greater advantages from medical and surgical science than the poor, and in proportion as this science is promoted will their sufferings be mitigated. This, he ought to know, is accomplished by "induction,"—proceeding from one discovered truth to another; and he should have been one of the most strenuous advocates for the removal of those barriers which yet prevent the majority of our profession from studying under the most favourable circumstances the diseases of our bodies. Leicester Infirmary, however, under the management of such gentlemen as Mr. Packe and Sir Henry Hallford, who showed himself a worthy supporter of his reverend friend, would be excluded from all participation in the honour of advancing the science of medicine by affording to the rising generation the means of instruction, while the faculty in the town must rest content with the experience obtained from private practice. Of this individually they cannot expect anything more than a limited amount, the lion's share falling to the hospital professionals, who find, to use the words of the committee, "that the honorary appointments are very great and important, as they tend to place their possessors almost invariably at the head of their profession."

This, we strongly suspect, lies at the bottom of the opposition to the appointment of additional medical officers, as the committee adds in their

persons, and the non-liability of all persons to pay who employed them.

If the foregoing plans are carried out with ability and energy, I feel confident immense results would follow. I am for putting our own shoulders to the wheel, and not waiting for the slow, apathetic, and cumbrous movement of a lethargic corporation. The evil is daily increasing to our pecuniary loss, and to the serious injury of the public health. When I inform you that there on my list (which does not, I fear, comprise half the number) eight hundred unqualified practitioners in the metropolis and within ten miles, you will allow it is time for us to be up and doing. There are one hundred and forty in the Tower Hamlets, and twenty-three in the parish of Bethnal-green alone.

Now, a subscription of two guineas per annum from each qualified practitioner in the Tower Hamlets would form a considerable fund, which, rightly applied, would produce astonishing results to the subscribers: for, if $\frac{1}{10}$ of the above number were carefully and vigorously attacked, the other locusts would take to flight, and adopt the prudent course of seeking safety in their proper sphere of bricklayers or railway police.

If these hints meet your approbation, I should feel obliged by their insertion in any form you may think most suitable, with such comments as your superior opportunities of information may supply.

I have the honour to remain

Your most obedient servant (in haste),

A PRACTITIONER WITH THREE TAILS.

Hackney-road, Sept. 27.

GOSSIP OF THE WEEK.

WAR-OFFICE, Oct. 1.—2nd Dragoons: Surg. Robert Dunkin Smyth, from the 87th Foot, to be Surg., vice John Wintarscale, who retires upon half-pay.—20th Foot: Staff-Surg. of the Second Class Isidore Anthony Blake, M.B., to be Surg., vice Fishbourne, who exchanges.—81st Foot: Assist.-Surgeon Charles Frederick Stephenson, M.D., from 9th Foot, to be Assist.-Surg., vice Schooles, promoted on the Staff.—87th Foot: Staff-Surg. of the Second Class William Leslie Langley, M.D., to be Surg., vice Smyth, appointed to the 2nd Dragoons.—Hospital-Staff: Surgeon Thomas Moore Fishbourne, M.D., from the 20th Foot, to be Staff-Surgeon of the Second Class, vice Blake, who exchanges.—Assist.-Surgeon Henry James Schooles, M.D., from the 81st Foot, to be Staff-Surgeon of the Second Class, vice Langley, appointed to the 87th Foot.

APOTHECARIES' HALL.—Gentlemen admitted members on Sept. 30: Horatio Coare Brenchley, Thomas Hood, Joseph Rushforth, Henry Fowler Jenkinson, Samuel Fowell, and George Bellasis Masfen.

CURIOUS CASE IN MEDICAL JURISPRUDENCE.—The *Gazette Medicale* relates the following facts in recent number:—"On the 6th of January last the body of a man was found lying in bed and in a state of combustion, by some persons who entered his bedroom in the morning. The chamber was filled with a dense smoke, and one of the witnesses asserted that he saw playing around the body of the deceased a small whitish flame, which receded from him as he approached. The clothes of the deceased and the coverings of the bed were almost entirely consumed; but the wood was only partially burnt. There were no ashes, and but a small quantity of vegetable charcoal; there was, however, a kind of mixed residue, altered by fire, and some pieces of animal charcoal, which had evidently been derived from the articulations. The deceased was in the habit of carrying lucifer-matches in his waistcoat pocket, and, according to his usual practice, he had had a hot brick placed at his feet when he went to bed the preceding evening. Two hours afterwards his son and daughter-in-law passed by the door of his room, but there was nothing which attracted their attention. It was only the following morning early that his grandson found

the body in the state described. The deceased was seventy-one years of age. He was not fat, nor was he addicted to drunkenness. The temperature of the air was low: there were no indications of electricity. The son and his wife were suspected of having murdered the deceased and burned the body in order to conceal the traces of the crime, and a Dr. Masson was commissioned to investigate the case. The body, which had been buried, was exhumed and examined. The cravat, partially burned, was still around the neck, and part of a sleeve of the night-shirt was found. The hands, completely burned, were only attached to the forearms by some carbonized tendons, which gave way on the slightest touch. The thighs were completely detached, so as to resemble a wilful mutilation but for the discovery of animal charcoal about them. From these facts Dr. Masson, considering it impossible to ascribe these changes to the effect of accidental burning, and that, under common circumstances, they could only be produced by a violent combustion continuing for some time, drew the inference that the burning must have resulted from some inherent cause in the individual, probably roused into activity by the hot brick placed at the feet of the deceased. The burning once commenced would be easily supported by the state of the tissues. Hence the case was, in his opinion, to be referred to the class of spontaneous combustion. It is said that Orfila coincided with M. Masson in this extraordinary opinion, and the accused were acquitted."

MANSLAUGHTER BY QUACK DOCTORS.—A young man, named John Duffy, a native of Endrin, in King's County, who was lately employed in the mercantile establishment of Mr. Timothy Bagnall, Ferbane, recently caught a cold, and went home to his friends at Endrin. While residing there, he was bled in the arm by a man named Tommy Egan, a rough country surgical practitioner, who, in the operation, punctured an artery beneath the vein. The limited skill of this hero of the lance rendered him indifferent to the injury he inflicted, consequently he adopted no means to repair his fault. In a short time the arm swelled, and the blood burst forth; when the infatuated people called in another quack named Connor, "a cure-all," who opened the wound with the end of a goose quill, removed the clotted blood, and poured in some of his quack medicines. This, however, seemed rather to increase the sufferings of the unfortunate man, the blood flowing excessively from the wound. His friends were then alarmed at the dangerous appearance of the wound, and called in Dr. Fry, of Ferbane, who, on beholding his perilous situation, desired that he should be removed to the infirmary here, at the same time putting a tourniquet on the arm to prevent the excessive flow of blood. In this state, and almost exhausted, the young man reached Parsonstown on Sunday week, when Dr. Peirce did all his power to save him; but, notwithstanding his efforts and extreme attention, he died on the following Tuesday. On Wednesday James Dillon, Esq., senior coroner, was called on by the authorities to hold an inquest on the body. On his arrival, he selected a respectable and intelligent jury according to the new law, after inflicting penalties on ten persons for non-attendance. The sister of the deceased was examined as to the various operations performed on her brother, and Dr. Peirce, who made a dissection. The jury returned a verdict of "Manslaughter" against Egan and Connor, alleging that the puncture and subsequent mismanagement were the immediate cause of death. The coroner then discharged the jury, and issued his warrant for the apprehension of the parties, one of whom (Connor) was committed to the county goal on Saturday last, by Messrs. Lauder and King, J. Ps.; but Egan decamped, and has up to the present eluded the vigilance of the police.—*King's County Chronicle*.

INTERESTING TO THE MEDICAL PROFESSION.—On Wednesday, Mr. P. T. Chambers, of Newcastle, appeared by Mr. Brevint, at the County Court, Gateshead, to recover £9, 1s. 6d. from Mr. Thomas Forman. The defendant was repre-

sented by Mr. Stoker, jun.—The plaintiff, who practises medicine and surgery, had been consulted by the defendant; and the sum claimed was the amount of his bill of charges. In proof of Mr. Chambers' title to recover, he was examined to show that he began his apprenticeship with the late Mr. Laidler, and concluded it with the late Mr. Maxwell—the latter of whom cancelled his indenture in March, 1815—ever since which time he had practised his profession on his own account. The cancelled indenture was produced; also a letter, purporting to be written by the defendant (and which, although not read, was understood to contain an acknowledgment of the debt); with, likewise, an "I. O. U." bearing the defendant's signature.—Mr. C. P. Henzell, surgeon, a witness for the defence, deposed that he went to Mr. Maxwell's as an apprentice in August, 1816, and found the plaintiff there. The plaintiff continued with Mr. Maxwell, for some time afterwards, as witness's senior apprentice.—Mr. W. C. Preston, surgeon, deposed that he went to Mr. Maxwell's in 1813. Mr. Chambers came subsequently, and was there as an apprentice when Mr. Henzell was bound.—Mr. Thomas Dove, solicitor, deposed that in May, 1815, he was articled to Mr. Donkin, whose office adjoined Mr. Maxwell's surgery. For a year or more afterwards he saw the plaintiff daily going to and fro as Mr. Maxwell's apprentice.—Mr. Forman, the defendant, deposed that for all the medicine and assistance he had from the plaintiff he paid him over the counter. The signature to the "I. O. U." was his, but when he wrote it the paper was blank. The plaintiff told him he liked to have his patients' names, and got him to write his name on a sheet of paper. The letter produced, and to which his name was attached, was not his writing.—The answer to all this evidence was a denial of the truth of Forman's statement, and an assertion that the plaintiff was freed from his indenture in March, 1815, through the kindness of Mr. Maxwell, and practised for himself, although the appearance of his being an apprentice was kept up.—Mr. Stoker called the attention of the judge to the endorsement on the indenture, which had apparently been tampered with; and his honour remarking that he could not get over the evidence for the defence, dismissed the case.—*Gateshead Observer*.

THE EPIDEMIC IN EDINBURGH.—The fever which has raged here so fearfully during the past summer does not appear to be assuming a more modified or less virulent aspect. On the contrary, by all accounts, the contagion appears to be increasing daily, and its victims are becoming so numerous as to give great cause for alarm, and to demand the adoption of such prompt and effectual steps as skill and experience can recommend, to mitigate, as far as possible, its dreadful effects. Of late, the epidemic has appeared in several instances in the middle and upper classes of the city, though its devastations are confined chiefly to the poor and destitute. On Monday Mr. Mackay, one of the assistant-inspectors of the poor for the city parish, fell a victim to the malady, which he caught only ten days previously in the discharge of his official duties. Mr. Mackay has been connected with the institution for ten years. This is the second assistant-inspector which the parochial board have lost within the last few months. We learn also that the mistress of the industrial school recently set on foot by the board fell a victim to fever some weeks ago; and that the master, Mr. Thomson, is at present lying ill of it. In fact, the operations of this institution are to be completely suspended for the present, and the building which was used for the purposes of the school is to be devoted to the reception of fever patients. To give some idea of the mortality from the disease at present, we may state that the number of paupers which the city parochial board alone have sent to the infirmary since the 1st of June to Monday last was 887, of whom no less than 485 died, 70 per cent. of these being fever cases. That the disease is fearfully increasing is evident from the fact that 466 of the

above 887 have been admitted since the 10th of August; and, above all, from the circumstance that at the present moment there are no fewer than 143 fever patients in various parts of the town, who, from want of accommodation, cannot be admitted into the infirmary. Nine-tenths of these are Irish, who have flocked to the charity workhouse from all parts of Scotland. The Royal Infirmary has long been inadequate to the demands made for admission within its walls, and though an additional large shed, capable of containing, we believe, from 80 to 100 beds, is the course of erection, that accommodation is even far short of what the present calamity so grievously necessitates. We understand that the medical committee of the parochial board intend to have an interview with the managers of the infirmary, with the immediate view of taking some decided steps to provide for those cases of fever which cannot at present be overtaken, and we have no doubt they will meet with the liberal support of the community. Fever has also attacked several of the police force, twelve of the constables being at present under its influence, and some of them are in a very wretched state.

THE YELLOW FEVER IN NEW ORLEANS.—The yellow fever continues to rage in New Orleans with terrible effect. We see announced amongst the deaths Archibald L. Dey, aged twenty-four, son of Mr. Anthony Dey, of this city; Mr. Marion Ward, son of the late Samuel Ward, of this city; Theo. Fiak Blake, late of Boston; Dr. B. Hull, Mr. John Patlethwaite, &c. The Howard Association is the title of a society formed for the aid and relief of the afflicted, and Messrs. Henry E. Lawrence and A. B. Coleman, of New Orleans, at present in this city, have been designated as its agents here. Donations for the relief of the suffering will be received by them at the Astor-house. The following, from the *Pionier* of the 5th of September, gives the latest intelligence of the progress of the disease:—"The past has been the most fatal week of the epidemic, which scourges us with a severity which is appalling. The interments for the week in the cemeteries of the city up to nine o'clock on Saturday morning were 533, of which 427 were of yellow fever; the corresponding numbers of the previous week were 442 and 311. Add the interments from New Orleans at Lafayette, 43 cases, and we have a total of interments for this city for one week of 578, being an average exceeding 82 each day. This awful mortality needs no comment. The reports of the Charity Hospital show a slight increase of admissions and deaths there. The total admissions for the week ending Saturday evening, at six o'clock, were 445, against 434 the previous week; while the deaths from yellow fever there during the same time were 128, against 92 the previous week. The discharges of yellow fever from the hospital the last week were 222. The weather during the week has been signally unpropitious, being extremely changeable. Several days have been cold for the season, keen north winds blowing. At the moment of writing, however, the weather is extremely warm and favourable, and we pray that it may continue so. The few details we have given above will better tell our absent friends the story of the sufferings of this doomed city than whole columns of comment, and we gladly dismiss the subject for a moment from our minds."

STRANGE DEATH.—A very melancholy sensation has been created in the parish of Cairney (Aberdeenshire) and neighbourhood by the death of a woman, under the following circumstances. She had been attending, as sick-nurse, on a young man suffering under malignant scarlet fever, and, in wiping the face of the sufferer, some of the purulent matter from his mouth came in contact with a pin-scratch on her hand. Her arm almost instantly became inflamed, and she was soon in an agony of extreme suffering and fever. Everything was tried to stay the process of mortification, but in vain. After some little time the arm was amputated; even this failed; and after a few more days of great distress the woman died.

PREVALENCE OF FEVER.—The existence of fever in Newcastle, caused by the influx of numerous bodies of peasantry from Ireland, was noticed some time ago; but within the last fortnight the disease has alarmingly increased. In Sandgate, Pandon, Walknoll, and Stockbridge, the places where the Irish poor are principally located, the disease has been very virulent. Out of 182 cases of sickness reported to the board of guardians last Friday (Sept. 24), by Mr. Newton, the district surgeon, 136 were stated to be ill of fever. Several other cases have likewise been reported to have occurred in Puddingchare, Head of the Side, Castle Garth, and Close; but in other parts of the town the state of health generally is good. The Fever Hospital, which has lately been considerably enlarged, is full of patients, there being at this time between sixty and seventy; and the consequence is that a great proportion of the sufferers have to be attended to, at much disadvantage and risk, at their respective and miserable abodes; and thus the disease is permitted to spread from family to family, from the want of a proper establishment to allow of their immediate removal. The board of guardians, aided by their officers, have been most prompt in their efforts to relieve the sufferers, and have fitted up the extensive premises in the upper part of the vagrant-ward for the reception of those patients who are convalescent, where every attention is paid to their wants. The medical officers of the several parishes have been unremitting in the discharge of their duties; and Mr. Newton, one of the medical officers, is at present labouring under the infection, besides his assistant, Mr. W. Swan, together with Mr. N'Nay, the medical officer for All Saints' east ward. Mr. Shield, surgeon, New Bridge, has been appointed by the board of guardians to fill the temporary vacancy occasioned by the illness of Mr. Newton. Among the relieving officers, Mr. Robson, of Westgate township, and Mr. Wilson, of All Saints' parish, are both indisposed, but, we understand, are in a fair way of recovery. The Rev. Messrs. Standen and Cullen, Catholic clergymen, have also caught the infection while visiting the sick and dying. The fever, up to this period, has principally been confined to the Irish paupers, whose condition, according to the report of the relieving officers, is truly wretched, the great majority of them having arrived in the town meanly clad and destitute, and are glad to take refuge in those dark and filthy abodes too common in Sandgate, where they exist but a short time, to propagate disease and misery.

By a royal decree, M. Charles Lunde is appointed to succeed M. Pariset, deceased, as a member of the Board of Health.

Dr. Richond des Brus, deputy, will succeed Dr. Montluc, deceased, as physician at the mineral baths, at Nérès.

It is announced that two general inspectors in the medical service are about to proceed to the western coast of Africa, to look after the health of those employed in our squadrons.

Dr. Maurin, of the Mediterranean steam-boats, has been appointed chevalier of the Order of St. Sylvestre, by his Holiness Pius IX.

The cholera is raging at Moscow. On the 17th of September several persons were picked up in the streets.

Dreadful fever is raging at Teheran. Dr. Bell, an English physician there, had obtained leave of absence, after a severe attack, and was returning home; but we learn the sad intelligence that he died before he quitted Asia, at Erzeroum.

The following is the list of applicants for the clinical chair vacant by the death of M. A. Bérrard:—MM. Langier, Jobert, Robert, Michon, Vidal (de Cassis), Malgaigne, Chassaignac, Josselin, Marchal (de Calvi), Huguier, Alquié (de Montpellier).

The members of the Administration of Hospitals in Paris are holding a consultation about establishing a colony for deserted children.

At the opening of the annual session of the Faculty this year, the address was pronounced by Professor Bérrard.

ADULTERATION OF OATMEAL.—At the Glasgow

Circuit Court of Justiciary, on Wednesday, Sept. 29, Alexander Bannatyne, grain-merchant, St. Vincent-street, Glasgow, was indicted for falsehood, fraud, and wilful imposition, in having mixed bran and thirds with oatmeal, supplied by the house of Bannatyne and Co. as oatmeal for the relief of the poor in the Highlands, in pursuance of a contract with the committee in Glasgow for the relief of Highland destitution. After the evidence had been heard, the jury delivered the following verdict:—"Guilty as libelled, with the exception of mixing with bran, but recommended the prisoner to the utmost leniency of the court, in consequence of the practice having been adopted by other parties in the trade." The Lord Justice Clerk sentenced him to be imprisoned four months from this date and pay a fine of £300, failing to pay which, at the expiry of that term, to suffer other four months' imprisonment. The prisoner was then removed.

OBITUARY.—On the 4th inst., at his residence, Tottenham, Middlesex, John Morgan, Esq., member of the council of the Royal College of Surgeons, and many years one of the surgeons of Guy's Hospital.—Aug. 21st, aged 36, of fever, Richard Mackenzie Hiddleston, Esq., resident medical officer at the House of Recovery, Leeds.—On the 2nd ult., at Trafalgar-cottage, Manor Hamilton, aged 62, James Dundas, Esq., R.N., F.R.C.S.L., surgeon to the dispensary, and medical attendant of the workhouse. Mr. Dundas contracted malignant typhus fever during his attendance in the temporary fever hospital. He was assistant-surgeon of H.M.S. Cyclops at the battle of Trafalgar, and on leaving the service he devoted a long and useful life to the cause of humanity and science; his loss will be long felt by the community and members of his own profession.—Sept. 5th, at Granard, aged 72, Dr. McCormick, medical attendant of the union workhouse.—Sept. 14th, at Doncaster, aged 46, of fever, caught in the discharge of his duties as medical officer to the Doncaster union workhouse, Robert Storrs, Esq., surgeon.—Sept. 19th, at Honiton, aged 40, from a tubercular deposition in the lungs brought into action by an attack of typhus fever, James Campbell, Esq., M.D.—Sept. 19th, at Baltinglass, of fever, John Johnston, Esq., medical officer to the union workhouse and district fever hospital. from the bar.—*Globe*.

MORTALITY TABLE.

For the Week ending Saturday, Oct. 2, 1847,

Causes of Death.	Total.	Average of 5 Summers.
ALL CAUSES.....	1143	940
SPECIFIED CAUSES.....	1140	935
Zymotic (or Epidemic, Endemic, and Contagious) Diseases.....	317	226
SPORADIC DISEASES.		
Dropsy, Cancer, and other Diseases of uncertain or variable Seat.....	150	103
Diseases of the Brain, Spinal Marrow, Nerves, and Senses.....	169	157
Diseases of the Lungs, and of the other Organs of Respiration.....	227	226
Diseases of the Heart and Blood-vessels.....	29	25
Diseases of the Stomach, Liver, and other organs of Digestion.....	80	94
Diseases of the Kidneys, &c.	8	8
Childbirth, Diseases of the Uterus, &c.	9	10
Rheumatism, Diseases of the Bones, Joints, &c. ...	4	7
Diseases of the Skin, Cellular Tissue, &c.	2	2
Old Age.....	35	50
Violence, Privation, Cold, and Intemperance.....	110	28

INDEX TO VOL. XVI.

- A.**
Aberdeen, King's College Regulations, 609
..... Marischal College, 609
..... University of St. Andrew's, 609
Abnormal condition of the blood, 397
Abolition of burials in towns, 463
Abscess of the liver treated by puncture, 395
..... neck, 61
..... new treatment of, by congestion, 599
..... subcutaneous, discharged through trachea, 576
Abstract of address delivered at the Hunterian School, by
Dr. C. J. B. Aldis, 641
Absence of kidney, 407
..... os tinctum, 237
Absorption and exhalation in animals and plants, 389
Abuse of ether, 482
Academy of Medicine, meetings of the, 15, 35, 58, 79, 96,
116, 136, 154, 175, 200, 216, 235, 267, 275, 296, 309, 333,

553, 575, 594, 619, 651
Accidental Ossification, 298
Accidents brought to London Hospital, statistics of, 13
Accident to Dr. Clinchall, 620
Acetate of morphia, poisoning by, 258
Acid, hydrocyanic, poisoning by, 380
..... syrup of, 437
..... lactic, purposes of, in the body, 555
Aene, M. Cazenave on, 511
Acnitis in rheumatism, 437
Act, the passengers, 581
Action of mercury on the system, 132, 153, 172, 213, 271,
293
..... lead in spinal irritation and diseases of the heart,
98
..... glands of the stomach, 554
..... physiological, of gravity, light, and heat, 488
..... electrical currents, 505
Actual cautery in aneurism by anastomosis, 576
Acute disease, last stage of, return of consciousness by
rapid vesication, 276
..... meningitis and hydrocephalus, 638
..... rheumatism, 495
..... simple dysentery, 578
Adams, Dr. on Neurosis, 11
Address of Mr. Skoy, 359
..... at St. Thomas's Hospital, by Mr. J. H. Green, 639
Adipocere, 554
Administering quinine, the best mode of, 397
Adult, sclerema of the, 651
Advantages of compression over ligature in aneurism, 596
Adynamic fever, Peyer's glands in, 375
Affections, nervous, 512
..... thoracic, and intermittent fever, 396
..... surgical elevation of diseased parts in, 554
Agent for resuscitating patients after inhaling ether, 122
..... remedial, oxide of silver as, 303, 307, 361
Air into veins, entrance of, 255
..... in the uterus, 298
Aitken, Mr., on injury of the head, 593
Albinism, 176
Albuminous urine, 333
Albuminuria, iodide of iron in, 495
Alkaline vegetable, a new, 638
..... urine in health, 531
Altering a diploma, 424
Alum as an emetic in group, 415
Alveolar cancer of the stomach, 278
Amara Iberis, properties of, 475
American patent, 378
..... inventors, 273
..... National Convention, 424, 503
Ammonia, benzoate of, in gout, 475
..... rapid vesication with, 436
Amputation, double, 258
..... inflammation of sheaths of tendons after, 510
..... number and results of the larger, at Monterey,
511
..... of penis, 505
Anatomical anomaly, 398
..... lesions in rheumatism, 456
Anatomy of the eye, 594
Analysis of the blood after inhalation of ether, 244

- Infection, prevention of, from dissection, 417
 Infirmary, Bedford, election of a physician to, 401, 403, 423
 Edinburgh, 123, 381
 Manchester, 158
 Eye, 164
 Inflamed spermatic cord stimulating hernia, 274
 Inflammation of fibrous structures, M. Gerdy on, 216
 kidney and puerperal convulsions, 577
 local, and circulation, influence of gravity on, 296
 lectures on, by Dr. Corrigan, 3, 54
 of sheaths of tendons, 510
 subacute, of the kidney, 399
 syphilitic, of the eyelid, 216
 Inflammatory diseases of the kidney, 399
 Influence of atmospheric electricity on the system, 333
 the brain and spinal marrow on the heart, 475
 periods of the day on births and deaths, 496
 weather on health, 496
 Influences, nervous, connection of, with electricity, 277
 Infringement of the Apothecaries' Act, 160
 Ingrowing nail, new operation for removal of, by Mr. Long, 650
 Inguinal hernia, strangulated, 473, 594
 Inhalation of ether, 15, 35, 58, 68, 95, 114, 123, 130, 136, 404, 575
 in cerebro-spinal meningitis, 333
 Dr. Hickman the first discoverer of, 561
 injurious effects of, 355
 state of the blood after, 244
 statistics of, in Paris, 196, 230, 251
 Iniquity of the poor law, 598
 Injection of ethereal vapour into the rectum, 373
 quinine into the stomach of dogs, 397
 various substances into arteries, 310
 Injections, iodine, in the cure of scabies, 375
 suppurated buboes treated by, 473
 Injuries of the diaphragm, 476
 Injurious effects from ergot of rye, 390
 Injury to the knee, clinical remarks on, 27
 of the head, 593
 to the membrana tympani producing general erethism, 258
 peculiar, of the upper end of the humerus, 457
 Inoculation in syphilitic buboes, 236
 Inquests, coroners', 361
 Inquest at Grantham, 119
 Hounslow, 179
 and position of medical officers of the service, 280
 on the Hickman family, 351
 at Putney, 441, 479, 480, 499
 Insalubrious arts, 415
 Insane, condition of the urine in, 357
 general paralysis of, 235
 Insanity, 638
 hereditary transmission of, 353
 Insensibility produced by ether, state of respiration in, 333
 Institute, the National, 21, 41, 105, 129, 242, 302, 321, 382, 478, 499, 516, 617
 Instrument, new, for applying pressure in popliteal aneurism, 334
 Insurance companies and the profession, 637
 Intercoastal neuritis, 276
 Interesting to the medical profession, 657
 Intermittent fever in Lower Normandy, 492
 and thoracic affections, 396
 Intermittents, quinine in, 12
 Intermittents, hasty, 244
 Internal carotid, aneurism of, 590
 strangulation of intestine cured by operation, 18
 use of nitrate of silver, 594
 Interpretation, Dr. Sherman's, of the Medical Registration Bill, 319
 Intestinal gases, Dumas on, 330
 secretions in cholera, composition of, 510
 Intestine, stricture of, in hernia, 588
 Intestines, fungi in, and the mouth, 298
 Intoxication from vapours in brass foundries, 651
 saturnine, 176
 Intrepidity, medical, 344
 Introduction of stones into the bladder, 275
 to Professor Matteucci's lectures, 340
 Inventors, American, 275
 of ethereal inhalation, 474, 651
 Invertebrata, psoriasis, 496
 Invisible spine supporter, 583
 Iodide of iron in albuminuria, 495
 potassium in hemiplegia, 438
 sulphur in cutaneous disease, 354
 Iodine injections used in scabies, 375
 used in removing iron from cornea, 277
 Ireland, hospitals and dispensaries in, 614
 the medical profession of, 443
 representations of physicians and surgeons of, 381
 Surgical Society of, 18, 40, 138
 Irish apothecaries and English chemists, 329
 medical protest, 439
 Government answer to, 461, 481
 Iron, tannate of, in chlorosis, 434
 Irritability, diminution of, 16
 Irritation, counter, in cholera, 2
 of mucous membrane, camphor in, 2
 Irritants, medusæ as, 635
 Ischuria neonatorum, 438
 renalis, 416
 Isle of Man, petition of physicians and surgeons of, 403
 Is the Society of Apothecaries in existence? 343
 J.
 Jack Ketch a medical man, 635
 Jackson, Mr., de motu sanguinis, 493
 on epilepsy, 414
 on a new arrangement of the bloodvessels, 215
 Jacksonian prize, 384
 Jacobi membrana, 596
 Jaw, lower, partial closure of the, 547
 removal of a tumour from, 63
 Jens, University of, 615
 Jenny Lind and hypnotism, 602

- anatomical lesions in, 456
- arthritis in, 437
- articular treatment of, 157
- with hypertrophy of both eyes, 455
- and orchitis, 47
- Ricord, M., clinical lectures by, 310
- Rigby, Dr., reports on diseases of females, 397, 468
- Rights, civil, & corporate rights, 316
- Ringworm cured by blisters, 218
- transmission of, from animals to man, 155
- Rodler and Bequerel on the blood in scurvy, 373
- Rolph, Mr., forgery of his name, 500
- Rosstock University, 615
- Roupeil, Dr., lectures on the materia medica, 305, 345, 381, 441, 483, 503, 583, 583, 583, 583
- Roux, Prof., on dislocation of elbow, 287
- exostosis, 118
- Royal College of Chemistry, 48
- Surgeons, England, 19, 120
- Berkshire Hospital reports, 152, 253, 347
- Free Hospital, 381, 536, 533, 599
- Medical and Chirurgical Society, 18, 63, 99, 337, 712, 356, 390, 456
- Royle, Dr., on congenital phymosis, 173
- Rupture of extensor tend in leg, 397
- furni before delivery, 375
- heart, 278
- spontaneous, of gravid uterus—absence of os tincm, 237
- short umbilical cord on delivery, 433
- Russell, cholera in, 615
- lunatic asylums in, 622
- Rye, ergot of, in hemorrhage, 294
- injurious effects from, 390
- Ryott, Dr., and Medical Directory, 343
- S.
- Sacculated œsophagus and stricture, 476
- Sacrum, gangrene of, cause of rapid death in, 341
- of an infant, singular tumour over, 274
- Salaries of poor-law doctors, 620
- Salines in cholera, 3
- Salivary secretion use of, 510
- Salts, Lpsom, bitter taste of, how removed, 435
- Same poison produces chancre and gonorrhœa, 277
- Samson among the Philistines, 498
- Sanguine, de motu, 493
- Sanitary commission, the new, 638
- reform, 120
- Sarcina ventriculi, 254
- Sarcosine, chemical composition of, 259
- Saturine intoxication, 175
- Scalp separation of, from erysipelas, 576
- Scarlatina, 297
- therapeutic remedies in, 113
- and variola, coexistence of, 346
- Scarlet fever, 2
- the urine in, 3
- School, Hunterian, address delivered at, by Dr. C. J. B. Aldie, 641
- Medical, Bristol, 255
- Schools, medical, of the United States, 124
- provincial, 613
- Schultz, Dr., on the group, 176
- Sciathe notch, dislocation of femur into, 40
- Science in Egypt, 622
- honours paid to, 304
- Sciences, Academy of, 15, 35, 58, 70, 96, 116, 216, 257, 276, 310, 333, 373, 390, 411, 435, 454, 474, 493, 510, 530, 558, 575, 594, 639, 651
- Scleritis of the œsophagus, 496
- Sclerema of the adult, 631
- Scleroma of cellular tissue in newborn infants, 456
- Scoffers, Dr., on Burton-on-I well poisoning case, 162
- Scottland, dispensaries and hospitals in, 614
- Scrofula, chlorosis, and consumption, 376
- Scrofulous disease of eyeball resembling malignant disease, 377
- ophthalmia, 301
- Scrotal hernia, large, dissection of a, 551
- Serorum, wound of the, 437
- Scurvy, causes of, 344, 631
- composition of the blood in, 373, 530
- condition of the blood in, 396
- epidemic of Nottingham, remarks on the, 392
- nature of, 631
- on the, 348, 441, 437, A
- organic changes of the system in, 277
- prognosis of, 299
- and typhoid fever, 435
- Searle, Dr., on the action of mercury on the system, 153
- ether insensibility, 114
- Second vaccination, 384
- Secondary prostatic calculus removed by perineal incision, 238
- Secrete perpetual, election of, 454, 553
- Secretion of tears in infants, 397
- Secretions, intestinal, in cholera, composition of, 510
- Section, Cæsarean, 532
- Seeds of datura stramonium, poisoning by, 650
- Select medical committee, 593
- Servitors, the Liverpool, their medical officers, and sick poor, 281
- Semmelweis, Mr., Corfe on, 432, 549, 570, 589, 648
- Senna with matico, in hemorrhage of bowels, 595
- Sensation, new method of suspending, 377
- Sensibility, 16
- reflex, 414
- Separation of scalp from erysipelas, 576
- Septum nasi, hypertrophy of, 593
- Septuaginta, imperfect, 401
- Sequelæ of bowel complaint of 1846, 27
- scarlatina, treatment of, 493
- Serres, M., on mercurial treatment in typhoid fever, 510
- Service, medical, of army and navy, 303, 438
- Session, the new, 618
- Sessional synopsis for London, 613
